Figure C-1–Packet transmission example

ANNEX D
(Informative)
Service sequence state control

The period of PSEM communications is defined in a series of "Service Sequence States." The use of each service may be restricted to one or more states. Specific services also cause transitions between states. The transition is implemented upon positive acknowledgement of the service. The recognized states include:

a) Base State—This is the state at which communication begins. At this point the default data transmission parameters apply.

b) ID State—Once the metering device has been identified, this is the state that is entered.

c) Session State—When a successful logon has been completed, this is the state achieved.

The relationship between PSEM services and service sequence states is:

Identification service requests are accepted at the base state only. Acceptance of an identification service request, <ok> transitions communications to the ID state. This service cannot originate from the metering device.

Wait service requests are accepted in the ID and session states. Acceptance of these requests do not result in any sequence state changes. This service can originate from either end of the communication channel.

Negotiate service requests are accepted in the ID state only. Acceptance of these requests do not result in any sequence state changes. Negotiated services are not implemented until after acceptance. This service cannot originate from the metering device.

Logon service requests are accepted at the ID state only. Acceptance of a logon service request, <ok> transitions communications to the session state. This service cannot originate from the metering device.

Security service requests are accepted at the session state only. Acceptance of these requests do not result in any sequence state changes. This service cannot originate from the metering device.

Read and write service requests are accepted in the session state only. Acceptance of these requests do not result in any sequence state changes. These services can originate from either end of the communication channel.

Logoff service requests are accepted at the session state only. Acceptance of a logoff service request, <ok> transitions communications to the ID state. This service can originate from either end of the communication channel.

Terminate service requests are accepted at the ID and session states. Acceptance of a terminate service request, <ok> transitions communications to the base state. This service can originate from either end of the communication channel.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The Kahn reference, Kahn, Robert E., "Advances in Packet Radio Technology," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978) (Kahn 1978), includes descriptions relating to station and station-less routing in a packet radio network.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Kahn 1978
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
received from said second network that are destined for said first network to said first network,	communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery,

The '516 Patent – Claims	Kahn 1978
	changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and

The '516 Patent – Claims	Kahn 1978
	writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In

The '516 Patent – Claims	Kahn 1978
path of a client of said first network to said server can be through one or more of other clients of said first network;	particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the

The '516 Patent – Claims	Kahn 1978
gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on

The '516 Patent – Claims	Kahn 1978
	the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496. Kahn's stations have a gateway functions to a point-to-point network, such as the internet, which would inherently involve the TCP/IP protocol, and Kahn cites to the Cerf and Kahn IEEE article defining TCP. At a minimum, it would have been obvious to use TCP/IP in the point-to-point protocol network in order to provide a well-known and reliable protocol.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet

The '516 Patent – Claims	Kahn 1978
	operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496.
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '516 Patent – Claims	Kahn 1978
network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on

The '516 Patent – Claims	Kahn 1978
	the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496. Kahn's stations have a gateway functions to a point-to-point network, such as the Internet, which would inherently involve the TCP/IP protocol, and Kahn cites to the Cerf and Kahn IEEE article defining TCP. At a minimum, it would have been obvious to use TCP/IP in the point-to-point protocol network in order to provide a well-known and reliable protocol. It also would have been obvious to include a packet type to packets received by the

The '516 Patent – Claims	Kahn 1978
	gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished

The '516 Patent – Claims	Kahn 1978
	using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	"As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table

The '516 Patent – Claims	Kahn 1978
	information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network.

The '516 Patent – Claims	Kahn 1978
	One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing. At a minimum, it also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point

The '516 Patent – Claims	Kahn 1978
	route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may

The '516 Patent – Claims	Kahn 1978
	be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed

The '516 Patent – Claims	Kahn 1978
	to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494.

The '516 Patent – Claims	Kahn 1978
	"[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496. Kahn's stations have a gateway functions to a point-to-point network, such as the Internet, which would inherently involve the TCP/IP protocol, and Kahn cites to the Cerf and Kahn IEEE article defining TCP. At a minimum, it would have been obvious to use TCP/IP in the point-to-point protocol network in order to provide a well-known and reliable protocol.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978

The '516 Patent – Claims	Kahn 1978
	at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known

The '516 Patent – Claims	Kahn 1978
	as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '516 Patent – Claims	Kahn 1978
	Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Kahn 1978
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which

	consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '314 Patent – Claims	Kahn 1978
	"A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A

The '314 Patent – Claims	Kahn 1978
	route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For

The '314 Patent – Claims	Kahn 1978
	example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit

	then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

The '314 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other

The '314 Patent – Claims	Kahn 1978
	stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

The '314 Patent – Claims	Kahn 1978
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '314 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '314 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said second network; and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
a second data packet receiver configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate

The '314 Patent – Claims	Kahn 1978
	(transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '314 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in

The '314 Patent – Claims	Kahn 1978
	some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The

The '314 Patent – Claims	Kahn 1978
a client node radio modem; and a client node controller; said client node controller implementing a process including receiving and transmitting data packets via said client modem;	resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	"The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery,

The '314 Patent – Claims	Kahn 1978
	changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A

The '314 Patent – Claims	Kahn 1978
	user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '314 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '314 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '314 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '314 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '314 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network; a digital controller coupled to said radio modem and to said network interface, said digital controller	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

The '314 Patent – Claims	Kahn 1978
communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate

The '314 Patent – Claims	Kahn 1978
	(transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '314 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a

The '314 Patent – Claims	Kahn 1978
	nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

	 Fig. 9. Point-to-point and broadcast routing.
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477.

The '314 Patent – Claims	Kahn 1978
	"The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
wherein said digital controller changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first second nodes, the path to the first node through the most robust additional second nodes, the path to	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or

The '314 Patent – Claims	Kahn 1978
the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '314 Patent – Claims	Kahn 1978
	"3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
13. A first node as recited in claim 12, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller converts data packets received from the first network and destined for the second network into a format used by the second network.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494.

The '314 Patent – Claims	Kahn 1978
	"[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure

The '314 Patent – Claims	Kahn 1978
	the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496.
14. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver implementing a process to receive a data packet from a second node of said wireless network, a first converter implementing a process to convert said data packet to a format used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network

The '314 Patent – Claims	Kahn 1978
network; and a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed

The '314 Patent – Claims	Kahn 1978
	to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream

The '314 Patent – Claims	Kahn 1978
	repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net

The '314 Patent – Claims	Kahn 1978
	[24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the

The '314 Patent – Claims	Kahn 1978
	packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '471 Patent – Claims	Kahn 1978
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which

The '471 Patent – Claims	Kahn 1978
	consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '471 Patent – Claims	Kahn 1978
	"A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A

The '471 Patent – Claims	Kahn 1978
	route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For

The '471 Patent – Claims	Kahn 1978
	example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station

The '471 Patent – Claims	Kahn 1978
	then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

The '471 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other

The '471 Patent – Claims	Kahn 1978
	stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be

The '471 Patent – Claims	Kahn 1978
	discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

The '471 Patent – Claims	**Kahn 1978**
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to

The '471 Patent – Claims	Kahn 1978
	each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as

The '471 Patent – Claims	Kahn 1978
	their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '471 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '471 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination.

The '471 Patent – Claims	Kahn 1978
	Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
4. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network

The '471 Patent – Claims	Kahn 1978
buffer in digital memory, and	routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed

The '471 Patent – Claims	Kahn 1978
	to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream

The '471 Patent – Claims	Kahn 1978
	repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net

The '471 Patent – Claims	Kahn 1978
	[24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the

The '471 Patent – Claims	Kahn 1978
	packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

The '471 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to

The '471 Patent – Claims	Kahn 1978
	each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as

The '471 Patent – Claims	Kahn 1978
	their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the

The '471 Patent – Claims	Kahn 1978
	header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to:	It would have been obvious to implement authentication of clients and maintenance of a client link tree.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	"With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '471 Patent – Claims	Kahn 1978
	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '471 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

The '471 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net

The '471 Patent – Claims	Kahn 1978
	and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may

The '471 Patent – Claims	**Kahn 1978**
	actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '471 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '471 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination.

The '471 Patent – Claims	Kahn 1978
	Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
12. A method as recited in claim 11,	It would have been obvious to implement authentication of clients and maintenance

The '471 Patent – Claims	Kahn 1978
wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network

The '471 Patent – Claims	Kahn 1978
	routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed

The '471 Patent – Claims	Kahn 1978
	to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream

The '471 Patent – Claims	Kahn 1978
	repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net

The '471 Patent – Claims	Kahn 1978
	[24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the

The '471 Patent – Claims	Kahn 1978
	packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '471 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to

The '471 Patent – Claims	Kahn 1978
	each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as

The '471 Patent – Claims	Kahn 1978
	their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the

The '471 Patent – Claims	Kahn 1978
	header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
16. A method as recited in claim 15, wherein said server process further comprises steps of:	It would have been obvious to implement authentication of clients and maintenance of a client link tree.

The '471 Patent – Claims	Kahn 1978
determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	"With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '471 Patent – Claims	Kahn 1978
process including receiving and transmitting data packets via said second node radio modem,	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '471 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

The '471 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net

The '471 Patent – Claims	Kahn 1978
	and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may

The '471 Patent – Claims	Kahn 1978
	actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

</table>

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '471 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '471 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination.

The '471 Patent – Claims	Kahn 1978
conditions.	Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
19. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

The '471 Patent – Claims	Kahn 1978
recited in claim 18 wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a

The '471 Patent – Claims	Kahn 1978
receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way

The '471 Patent – Claims	Kahn 1978
	that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are

The '471 Patent – Claims	Kahn 1978
	rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by

The '471 Patent – Claims	Kahn 1978
	the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is

The '471 Patent – Claims	Kahn 1978
	input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978

selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '471 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '471 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination.

The '471 Patent – Claims	Kahn 1978
	Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
22. A wireless system as recited in	It would have been obvious to implement authentication of clients and maintenance

The '471 Patent – Claims	Kahn 1978
claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are

The '471 Patent – Claims	Kahn 1978
second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as

The '471 Patent – Claims	Kahn 1978
	a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path.

The '471 Patent – Claims	Kahn 1978
	To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80.

The '471 Patent – Claims	Kahn 1978
	"As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '471 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
the first node process further comprises maintaining a second node link tree having second node link entries.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

The '471 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
32. A wireless system as recited in claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The

	detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for

The '471 Patent – Claims	Kahn 1978
authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
send/receive data buffer in digital memory, and	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route

The '471 Patent – Claims	Kahn 1978
	the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve

The '471 Patent – Claims	Kahn 1978
	table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

"Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '471 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '471 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '471 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '471 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
maintaining a second node link tree having second node link entries at the first node.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The

The '471 Patent – Claims	Kahn 1978
	detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic;	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from

The '471 Patent – Claims	Kahn 1978
	each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '471 Patent – Claims	Kahn 1978
	This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and

The '471 Patent – Claims	Kahn 1978
	maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the

The '471 Patent – Claims	Kahn 1978
	packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.

The '471 Patent – Claims	Kahn 1978
receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes to the respective client node.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate

The '471 Patent – Claims	Kahn 1978
	routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact

The '471 Patent – Claims	Kahn 1978
	time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496. "D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms

The '471 Patent – Claims	Kahn 1978
	The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496.

The '471 Patent – Claims	Kahn 1978

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	Kahn 1978
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which

The '496 Patent – Claims	Kahn 1978
	consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '496 Patent – Claims	Kahn 1978
	"A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A

The '496 Patent – Claims	Kahn 1978
	route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For

The '496 Patent – Claims	Kahn 1978
	example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit

The '496 Patent – Claims	Kahn 1978
	reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients;	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station

The '496 Patent – Claims	Kahn 1978
and	then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other

The '496 Patent – Claims	Kahn 1978
	stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In

The '496 Patent – Claims	Kahn 1978
	particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination

The '496 Patent – Claims	Kahn 1978
	station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483.

The '496 Patent – Claims	Kahn 1978
	Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
maintain a client link tree having client link entries representing each of the plurality of clients.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current

The '496 Patent – Claims	Kahn 1978
	overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which

The '496 Patent – Claims	Kahn 1978
radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication

The '496 Patent – Claims	Kahn 1978
	failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the

The '496 Patent – Claims	Kahn 1978
	network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the

The '496 Patent – Claims	Kahn 1978
	packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

The '496 Patent – Claims	Kahn 1978
each of the clients to the respective clients.	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The

The '496 Patent – Claims	Kahn 1978
	detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for

The '496 Patent – Claims	Kahn 1978
said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device

The '496 Patent – Claims	Kahn 1978
	in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly

The '496 Patent – Claims	Kahn 1978
	attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the

The '496 Patent – Claims	Kahn 1978
	remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

The '496 Patent – Claims	Kahn 1978
	 **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. Communication across a stationless region.

The ‘496 Patent – Claims	Kahn 1978
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	“A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions).” Kahn 1978 at 1469. “Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible.” Kahn 1978 at 1477. “Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module.” Kahn 1978 at 1488. “The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2].” Kahn 1978 at 1494.

The '496 Patent – Claims	Kahn 1978
	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be

The '496 Patent – Claims	Kahn 1978
	dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally

The '496 Patent – Claims	Kahn 1978
	inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source

The '496 Patent – Claims	Kahn 1978
	of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall

The '496 Patent – Claims	Kahn 1978
	connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information

The '496 Patent – Claims	Kahn 1978
	in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled

The '496 Patent – Claims	Kahn 1978
	by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to

The '496 Patent – Claims	Kahn 1978
	discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978

Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

The '496 Patent – Claims	Kahn 1978
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '496 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the

The '496 Patent – Claims	Kahn 1978
not already in said client link tree.	desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-

The '496 Patent – Claims	Kahn 1978
	point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483.

The '496 Patent – Claims	Kahn 1978
	"The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

The '496 Patent – Claims	Kahn 1978
	 **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will

The '496 Patent – Claims	Kahn 1978
	wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup

The '496 Patent – Claims	Kahn 1978
	packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio,

The '496 Patent – Claims	Kahn 1978
	summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically)

The '496 Patent – Claims	Kahn 1978
	and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range

The '496 Patent – Claims	Kahn 1978
	of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each

The '496 Patent – Claims	Kahn 1978
	station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station

The '496 Patent – Claims	Kahn 1978
	which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

The '496 Patent – Claims	**Kahn 1978**
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

"When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination

The '496 Patent – Claims	Kahn 1978
	station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483.

The '496 Patent – Claims	Kahn 1978
	Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
maintains a client link tree having client link entries representing each of the plurality of clients.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current

The '496 Patent – Claims	Kahn 1978
	overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which

The '496 Patent – Claims	Kahn 1978
	collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication

The '496 Patent – Claims	Kahn 1978
	failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the

The '496 Patent – Claims	Kahn 1978
	network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the

The '496 Patent – Claims	Kahn 1978
	packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	**Kahn 1978**
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

	attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the

The '496 Patent – Claims	Kahn 1978
	remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated

The '496 Patent – Claims	Kahn 1978
	round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

The '496 Patent – Claims	Kahn 1978
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '496 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.

The '496 Patent – Claims	Kahn 1978
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information?

The '496 Patent – Claims	Kahn 1978
	One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and

The '496 Patent – Claims	Kahn 1978
	by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a

The '496 Patent – Claims	Kahn 1978
	packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

The '496 Patent – Claims	Kahn 1978
	 Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

The '496 Patent – Claims	Kahn 1978
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494.

The '496 Patent – Claims	Kahn 1978
	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn

The '496 Patent – Claims	Kahn 1978
	1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup

The '496 Patent – Claims	Kahn 1978
	packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio,

The '496 Patent – Claims	Kahn 1978
	summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically)

The '496 Patent – Claims	Kahn 1978
	and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range

The '496 Patent – Claims	Kahn 1978
	of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each

The '496 Patent – Claims	Kahn 1978
	station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In

The '496 Patent – Claims	Kahn 1978
	particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination

The '496 Patent – Claims	Kahn 1978
	station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483.

The '496 Patent – Claims	Kahn 1978
	Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current

The '496 Patent – Claims	Kahn 1978
	overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
17. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which

The '496 Patent – Claims	Kahn 1978
	collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication

The '496 Patent – Claims	Kahn 1978
	failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the

The '496 Patent – Claims	Kahn 1978
	network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the

The '496 Patent – Claims	Kahn 1978
	packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device

The '496 Patent – Claims	Kahn 1978
	in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly

The '496 Patent – Claims	Kahn 1978
	attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the

The '496 Patent – Claims	Kahn 1978
	remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated

The '496 Patent – Claims	Kahn 1978
	round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

The '496 Patent – Claims	Kahn 1978
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '496 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the

The '496 Patent – Claims	Kahn 1978
is not already in said client link tree.	desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-

The '496 Patent – Claims	Kahn 1978
	point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483.

The '496 Patent – Claims	Kahn 1978
	"The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):

The '496 Patent – Claims	Kahn 1978
	Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):  Fig. 11. Communication across a stationless region.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494.

The '496 Patent – Claims	Kahn 1978
	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn

The '496 Patent – Claims	Kahn 1978
	1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup

The '496 Patent – Claims	Kahn 1978
	packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio,

The '496 Patent – Claims	Kahn 1978
	summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically)

The '496 Patent – Claims	Kahn 1978
nodes,	and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range

The '496 Patent – Claims	Kahn 1978
	of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each

The '496 Patent – Claims	Kahn 1978
	station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

The '496 Patent – Claims	Kahn 1978
	"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the

The '496 Patent – Claims	Kahn 1978
	network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain

The '496 Patent – Claims	Kahn 1978
	neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination.

The '496 Patent – Claims	Kahn 1978
conditions.	Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
23. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

The '496 Patent – Claims	Kahn 1978
recited in claim 21, wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a

The '496 Patent – Claims	Kahn 1978
	stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way

The '496 Patent – Claims	Kahn 1978
	that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are

The '496 Patent – Claims	Kahn 1978
	rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by

The '496 Patent – Claims	Kahn 1978
	the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is

The '496 Patent – Claims	Kahn 1978
	input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '496 Patent – Claims	Kahn 1978
	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may

The '496 Patent – Claims	Kahn 1978
	actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978

maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or

The '496 Patent – Claims	Kahn 1978
	processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481.

The '496 Patent – Claims	Kahn 1978
	"3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in

The '496 Patent – Claims	Kahn 1978
	its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469.

The '496 Patent – Claims	Kahn 1978
receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	"Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it

The '496 Patent – Claims	Kahn 1978
	performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along

The '496 Patent – Claims	Kahn 1978
	the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the

The '496 Patent – Claims	Kahn 1978
	station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an

The '496 Patent – Claims	Kahn 1978
	operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

maintaining a second node link tree having second node link entries representing each of the plurality of second nodes,	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes,	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or

The '496 Patent – Claims	Kahn 1978
	processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in some link." Kahn 1978 at 1481.

The '496 Patent – Claims	Kahn 1978
	"3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.
the second node configured to implement a second node process including: sending and receiving data packet via a second node wireless radio; maintaining a send/receive data buffer in a digital memory; and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route

The '496 Patent – Claims	**Kahn 1978**
	the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve

The '496 Patent – Claims	Kahn 1978
	table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '496 Patent – Claims	Kahn 1978
	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and

The '496 Patent – Claims	Kahn 1978
	control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

	 Fig. 9. Point-to-point and broadcast routing.
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which

The '496 Patent – Claims	Kahn 1978
	collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication

The '496 Patent – Claims	Kahn 1978
	failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the

The '496 Patent – Claims	Kahn 1978
	network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the

The '496 Patent – Claims	Kahn 1978
	packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
the first node comprising: a first node controller; and a first node radio modem, wherein said first node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting data packets via said first node radio modem; and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '496 Patent – Claims	Kahn 1978
	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net

The '496 Patent – Claims	Kahn 1978
	and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may

The '496 Patent – Claims	Kahn 1978
	actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
35. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

The '496 Patent – Claims	Kahn 1978
recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate

	(transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '496 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '496 Patent – Claims	Kahn 1978
	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a

The '496 Patent – Claims	Kahn 1978
	nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477.

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	"The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network

The '496 Patent – Claims	Kahn 1978
	routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed

The '496 Patent – Claims	Kahn 1978
	to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream

The '496 Patent – Claims	Kahn 1978
	repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net

The '496 Patent – Claims	Kahn 1978
	[24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the

The '496 Patent – Claims	Kahn 1978
	network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the

The '496 Patent – Claims	Kahn 1978
	packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

<table>
<tr><th>The '496 Patent – Claims</th><th>Kahn 1978</th></tr>
<tr><td></td><td>route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483.

Kahn 1978 at 1484 (Fig. 10):

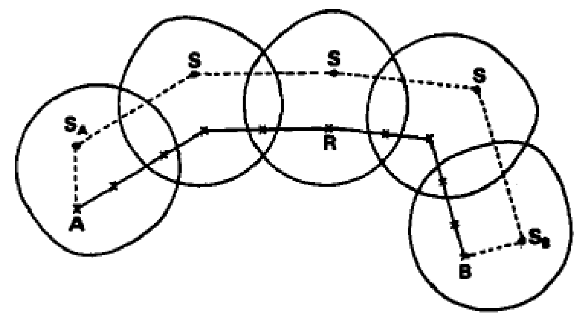

Fig. 10. Route finding and route setup with multiple station operation.

"For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484.

"A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely</td></tr>
</table>

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479.

The '496 Patent – Claims	Kahn 1978
	"From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The

The '496 Patent – Claims	Kahn 1978
	detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic;	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "With the addition of a communication security function, the packet radio net would then provide an integrated communication, navigation, and identification system for

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	secure tactical use." Kahn 1978 at 1470-71. "For any given transmitted packet, a sequence of codes is constructed from this finite code set according to a nonlinear secure algorithm. The sequence constructed depends on the slot number during which transmission begins and certain other parameters used by the algorithm. Use of this technique allows a good algorithm operating at low power and low speed to specify a high speed chip stream having the desired unpredictability to an observer outside of the system." Khan 1978 at 1492.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume

The '496 Patent – Claims	Kahn 1978
	topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to

The '496 Patent – Claims	Kahn 1978
	each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. If both users are fixed, the destination

The '496 Patent – Claims	Kahn 1978
	station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of

The '496 Patent – Claims	Kahn 1978
	selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence

The '496 Patent – Claims	Kahn 1978
	number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
maintain a client link tree having client link entries representing each of the plurality of client nodes.	"[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477. "The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current

The '496 Patent – Claims	Kahn 1978
	overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "[34] V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," this issue, pp. 1386-1408." Kahn 1978 at 1496.

The '496 Patent – Claims	Kahn 1978
	"D. lntemetting The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "H. Reliable Delivery Mechanisms The inherent undependability of a mobile radio channel requires an end-to-end protocol to provide reliable operation. For internal network control traffic (nonuser traffic), where perhaps one outstanding unacknowledged packet is sufficient, a highly efficient but specially designed protocol suffices. For intranet user traffic, or internet operation, a more flexible and higher performance protocol is desirable. We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking. In this case the user's terminal could be equipped with a microprocessor-based device known as a Terminal Interface Unit (TIU) which performs the end-to-end protocol, and any local support for the terminal (e.g., local echoing, formatting). The TIU interfaces directly to the digital unit of a packet radio. Within the PRNET, stations and radios need to communicate control packets reliably. For example, the regular reports from each radio to the station are used to validate the radio's continued availability. Without an effective recovery procedure the station could declare a perfectly good radio to be out of order and remove it from service if several of its reports were lost consecutively. Similarly, parameter change packets from the station to the radio should be delivered reliably since these are used to set dynamically important radio parameters, such as the retransmission interval or

The '496 Patent – Claims	Kahn 1978
	the maximum number of allowed retransmissions. The Station-PR Protocol (SPP) provides the reliable delivery mechanism." "By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn 1978 at 1494. "[38] V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648, May 1974." Kahn 1978 at 1496.
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from

The '496 Patent – Claims	Kahn 1978
	each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet.

The '496 Patent – Claims	Kahn 1978
	This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and

The '496 Patent – Claims	Kahn 1978
	maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the

The '496 Patent – Claims	Kahn 1978
	packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):  Fig. 9. Point-to-point and broadcast routing.

The '496 Patent – Claims	Kahn 1978
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an

The '496 Patent – Claims	Kahn 1978
	ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it

The '496 Patent – Claims	Kahn 1978
	can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each

The '496 Patent – Claims	Kahn 1978
	neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation.

The '496 Patent – Claims	Kahn 1978
	"For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the

	normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a

The '496 Patent – Claims	Kahn 1978
	packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be

The '496 Patent – Claims	Kahn 1978
	dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the

The '496 Patent – Claims	Kahn 1978
	packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity." Kahn 1978 at 1479. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484.
receiving information identifying the selected transmission path from each of the plurality of clients, determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios

The '496 Patent – Claims	Kahn 1978
	have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range

The '496 Patent – Claims	Kahn 1978
	of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening

The '496 Patent – Claims	Kahn 1978
	stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
44. The server of claim 42, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "[E]ach station is aware of all operational radios in the network. The stations discover

The '496 Patent – Claims	Kahn 1978
	the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network." Kahn 1978 at 1477. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information

The '496 Patent – Claims	Kahn 1978
	in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile, a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to

The '496 Patent – Claims	Kahn 1978
	obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "From the summary ROP's, each station knows the identity of its neighboring stations and a point-to-point route to each radio labeled by itself and a neighbor." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup

The '496 Patent – Claims	Kahn 1978
	procedure described earlier in this section. This process is illustrated in Fig. 10. The route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  **Fig. 10. Route finding and route setup with multiple station operation.** "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet

The '496 Patent – Claims	Kahn 1978
	appends its own selector to the data field, stores the information which uniquely identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
45. A first node for use in wireless network system including a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate

The '496 Patent – Claims	Kahn 1978
	(transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470. "The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each

The '496 Patent – Claims	Kahn 1978
	source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482. "A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480.

The '496 Patent – Claims	Kahn 1978
	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477.

The '496 Patent – Claims	Kahn 1978
	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn 1978 at 1479. "When a station is first connected to an operational packet radio, it will soon hear an ROP from that radio over the host interface after which the station will promptly 'label' the radio. The labeling process consists of first determining and then supplying the radio with a route (i.e., a set of selectors) to the station. In this first step, the task is trivial since the route to the station is via the host interface. In principle, once labeled, the packet radio periodically will continue to send its ROP's over the host interface to the station along with the less frequent summary ROP's. From the status information in these ROP's, the station will learn which radios are in direct communication range of its radio." Kahn 1978 at 1482. "The radio directly connected to the station is said to be at level 0 with respect to its station. All radios in direct communication range of the level 0 radio and not directly attached to the station are said to be at level l with respect to the station. Similarly, a radio in communication range of a level n-1 radio which is not itself already at level n-

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	1 or less is said to be at level n. A radio may be at different levels with respect to different stations, and its levels may change during mobile operation. A level simply indicates the minimum number of radio hops to the station and does not otherwise affect packet routing." Kahn 1978 at 1482. "Each radio has table space (labeling slots) for storing routes to several stations and by design the number of slots in each radio limits the number of stations that are allowed to label it. The route from a radio to a station is supplied by that station via the labeling process. Two stations which have labeled a common repeater are known as neighbors." Kahn 1978 at 1482. "One having labeled a radio, the station must relabel the radio within a given time or the labeling slot entry will expire. These entries are timed out (relatively slowly) by the radio, and the age of each entry is reported in its status reports. A station will always fail to successfully label a repeater which has no available labeling slots, but it can refresh an existing entry of its own at any time. A slot whose entry has expired is not erased by the radio (the route is not normally used either) but it may be overwritten by another station if no other labeling slots in the radio are free. In principle, a radio could be provided with diverse routes to a given station for applications such as mobile hand-off." Kahn 1978 at 1482. "We net [sic, next] describe routing through the multistation environment. Each station is assumed to know which radios it has labeled, but must inquire of other stations to learn the whereabouts of other radios (and their users). This inquiry is assumed to take place upon request by a user via a broadcast to all stations via neighboring stations. The inquiry process also provides the destination station with a set of selectors for a point-to-point route to the destination station from the originating user (if fixed) or station (for mobile users). If both users are highly mobile,

The '496 Patent – Claims	Kahn 1978
	a point-to-point route will be established between the two end stations which will individually handle the final distribution. If both users are fixed, the destination station will choose the last few selectors from among the radios it has labeled to obtain a point-to-point route directly between the two end users (with no intervening stations) and will supply it to the destination user. The actual point-to-point route setup is initiated by the destination user in this case, rather than by the destination station as was the case for mobile users. If one user is fixed and one user is highly mobile, the resulting point-to-point route will be between the fixed user and the remote station which will handle local distribution for the mobile user." Kahn 1978 at 1483. "The route selection process takes place as follows. A user's packet radio generates a packet for a destination outside the control of his station and his radio routes it to an appropriate local station (e.g., the closest one according to some metric). The station converts this packet into several distinct route finding packets which it sends to each neighboring station via some repeater jointly labeled by both stations. The conversion involves adding to the packet the station ID and a list of selectors from the user to the· jointly labeled repeater. When the packet is received by the neighboring station, it checks to see if the specified destination user is under its control. If not, it again converts the packet into several distinct packets by adding its own ID and a list of selectors from the original jointly labeled repeater to another repeater jointly labeled by a station not previously visited by the packet. If the packet arrives at a station which has just previously handled the same request via another route, it will be discarded by that station. In this way, one or more route finding packets will eventually arrive at a station which has labeled the destination user and will contain a composite list of selectors. The destination station then passes a complete list of selectors to the destination user's packet radio which initiates the route setup procedure described earlier in this section. This process is illustrated in Fig. 10. The

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	route finding path is shown as a series of dotted lines and the point-to-point route is shown as a series of solid lines." Kahn 1978 at 1483. Kahn 1978 at 1484 (Fig. 10):  Fig. 10. Route finding and route setup with multiple station operation. "For stationless operation, it is highly desirable for the radios to determine acceptable point-to-point routes, even if they only remain acceptable for short periods of time. In a technique that is very similar to multistation route finding, broadcasting can be used to find point-to-point routes which may be usable if the radio links are relatively stable. The repeater and terminals in the network cooperate with each other to discover and set up routes in three phases." Kahn 1978 at 1484. "A route finding packet is broadcast from the source PR when its attached device attempts to communicate with a destination for which a route is not yet known. This packet contains the source selector, the desired destination selector, and a sequence number which insures uniqueness. Any PR which hears the route finding packet appends its own selector to the data field, stores the information which uniquely

The '496 Patent – Claims	Kahn 1978
	identifies the packet, increments a 'hop' count in the packet and rebroadcasts it." Kahn 1978 at 1484. "Once the route finding packet arrives at the destination PR, it contains the estimated round-trip delay for a route which works in both directions. The destination PR will wait long enough to receive most of these packets (which may have travelled over different routes), will select the route with minimum delay, and will store this as the best route." Kahn 1978 at 1484. "Since the path discovered above may involve a very large number of selectors, it is clear that not all routing information can be stored in the data packets themselves. Some of the routing information must be stored in the intermediate PR's along the route. This is accomplished by a route setup procedure which is nominally identical to that which is used in the operational station case. A route setup packet is sent from the digital unit of the destination. PR which traverses the route specified in the selected route. This packet causes renewal table entries to be written in the intermediate PR's (in a table indexed by source and destination). Once this route setup packet arrives back at the source PR, the entire route is set up in both directions and we proceed to the final phase." Kahn 1978 at 1484. Kahn at 1485 (Fig. 11):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 11. Communication across a stationless region.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions)." Kahn 1978 at 1469. "Aspects of the network protocols (such as the radio acknowledgment procedures) which must be performed by each radio would be distributed among all radio elements. However, all network control protocols which can have global effect are specifically initiated by one or more entities in the network called stations. The resulting network control thus takes the form of a two level hierarchical system. The normal mode of operation utilizes a single station or multiple station. However, a stationless mode is also possible." Kahn 1978 at 1477. "Functions provided within the station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a

The '496 Patent – Claims	Kahn 1978
	debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn 1978 at 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]." Kahn 1978 at 1494. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6). For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. In a half duplex mode of operation, a radio may be transmitting or receiving, but not both simultaneously. In the remainder of this paper we assume that each radio operates as a half duplex transceiver in the common frequency band." Kahn 1978 at 1477. "The packet radio network structure should be capable of internetting in such a way that a user providing a packet address in another net can expect his network to route the associated packet to a point of connection with the other net or to an intermediate (transit) net for forwarding. Similarly, arriving internet packets should also be routed to the local user." Kahn 1978 at 1470.

The '496 Patent – Claims	Kahn 1978
	"The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station." Kahn 1978 at 1477. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "A renewal point is a PR along the route of a packet where the route (as specified in its header) may be altered. In point-to-point routing, the header contains fields which identify the next few designated repeaters along the path to a specified destination. Every repeater on a point-to-point route can act as a renewal point where these fields are rewritten. Two reasons for identifying more than just the next repeater in the header are to allow a detour via an alternate repeater in the event of failures along the designated path and to allow some repeaters not to serve as renewal points. The detour must be such that it eventually rejoins the designated path. To function as a renewal point for a point-to-point route, a repeater must have a renewal table containing the next few designated repeaters for that route. When a packet arrives at the next downstream repeater for relaying, its routing fields are rewritten in the header according to the current renewal table entries. To conserve table space, each repeater maintains, at most, one table entry for each source/destination PR pair. In addition, the table must identify the last few upstream repeaters on the path so that the source can be notified in the event of communication failures at any point of the path." Kahn 1978 at 1482.

The '496 Patent – Claims	Kahn 1978
	"A packet may also contain an entire path of route selectors in the text of the packet. This case may be distinguished by a special bit in the packet header which indicates that the text contains all the route selectors. Such a packet is known as a route setup packet and is used to initialize or refresh the renewal table entries in each repeater. Upon receipt of a route setup packet, a repeater extracts the renewal table information (normally a few entries) from the entire list of selectors in the text and writes it into the renewal table. The contents of a route setup packet are normally inserted by the digital unit of the destination PR. Any packet may be a route setup packet, subject only to the maximum packet length constraints of the network. A route setup packet may also contain data." Khan 1978 at 1482. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net

The '496 Patent – Claims	Kahn 1978
	and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. Several nearby repeaters may

The '496 Patent – Claims	Kahn 1978
	actually hear the packet, but only one repeater (which we call the next downstream repeater) will typically be identified to relay it. The other repeaters, will discard the packet. The packet will then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio. At each repeater, the packet is stored in memory until a positive acknowledgment is received from the next downstream repeater or a time-out occurs." Kahn 1978 at 1477. "Received packets are buffered in one of the receiver's descramblers prior to bit reordering and storage of the packet in processor memory under control of a DMA channel. Two receive descrambler/DMA channels are provided to allow reception of two successive packets with minimum interpacket arrival time." Kahn 1978 at 1492. Kahn 1978 at 1480 (Fig. 9):

Exhibit B1 – Invalidity Chart for Brownrigg Family based on Kahn 1978

The '496 Patent – Claims	Kahn 1978
	 Fig. 9. Point-to-point and broadcast routing.
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	"The functions of a station are associated with global management of the radio net [24] . Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. The station determines the route to each of these radios and plays an active role in initializing, organizing, and maintaining the operational network. In particular, all routes are assigned by the station to minimize PR cost and complexity. PR's are not required to store information about every other PR and terminal device in the network. One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR 's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio,

The '496 Patent – Claims	Kahn 1978
	summarized, and regularly sent to the station along with other status information. For example, each radio reports which other radios it can hear along with raw or processed information for the station to determine the quality of the transmission path between these radios. The station then deduces the overall connectivity of the network (we assume topologically rather than topographically) and determines good routes to itself from each of the radios in its subset. The station then distributes to each radio in its subset the route from that radio to the station. This process is known as labeling. The neighbor table is maintained by each PR whether or not an operational station is present and can be used in a stationless mode if necessary." Kahn 1978 at 1477. "In the event that one or more stations are available in the net and a point-to-point route fails (e.g., an intermediate repeater fails) the existing traffic on that route can be diverted to the station for forwarding to the final destination. The station must recompute a good route to the destination before it can forward the packet. Alternate routing is performed by the PR, when necessary, using parameters assigned by the station. Multiple receivers are allowed to forward a packet around a failed temporarily inaccessable repeater." Kahn 1978 at 1479-80. "As network conditions change (terminal movement, repeater failure or recovery, changes in hop reliability, and changes in network congestion) routes will be dynamically reassigned by the station to satisfy the minimum-delay criteria." Kahn 1978 at 1480. "If there was an operational station on the net, the PR's would send summary ROP's directly to the station at appropriate times (on a point-to-point route) to convey the current labeling information and also the neighbor table information. This is done both periodically and upon detection by the PR of a possibly significant change in

The '496 Patent – Claims	Kahn 1978
	some link." Kahn 1978 at 1481. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's, and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn 1978 at 1494.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	The Jubin References
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow

The '516 Patent – Claims	The Jubin References
network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. The '516 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '516 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '516 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

	observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
2. A server as recited in claim 1, wherein the second network is a	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the

The '516 Patent – Claims	The Jubin References
TCP/IP protocol network.	DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23.
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23.

The '516 Patent – Claims	The Jubin References
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "One special type-of-service is offered to users. It provides lower delay, and thus higher throughput, but less reliability and was designed primarily for packetized speech. A user can invoke speech type-of-service on a packet-by-packet basis via the speech type-of-service flag in the ETE header." Jubin and Tornow at 30.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium,

The '516 Patent – Claims	The Jubin References
for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and

<tr><th>The '516 Patent – Claims</th><th>The Jubin References</th></tr>
<tr><td></td><td>
"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23.

"[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25.

"If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25.

"In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25.

"In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22.

Fig. 2:

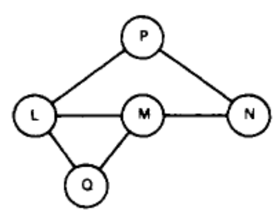

Fig. 2. Small packet radio network.
</td></tr>
</table>

The '516 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "One special type-of-service is offered to users. It provides lower delay, and thus

The '516 Patent – Claims	The Jubin References
	higher throughput, but less reliability and was designed primarily for packetized speech. A user can invoke speech type-of-service on a packet-by-packet basis via the speech type-of-service flag in the ETE header." Jubin and Tornow at 30. "Packet radio networking technology applies the packet switching class of communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88.

The '314 Patent – Claims	The Jubin References
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and

The '314 Patent – Claims	The Jubin References
	application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '314 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '314 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Fig. 2. Small packet radio network.

“In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway.” Jubin and Tornow at 22-23.

“The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination.” Jubin and Tornow at 23.</td></tr>
</table>

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '314 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). 	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '314 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '314 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '314 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a radio transmission path to said server node that is one of a direct link to said server node and an indirect link to said server node through at least one other client node;	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '314 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '314 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '314 Patent – Claims	The Jubin References
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	"Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23.

The '314 Patent – Claims	The Jubin References
	"After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network;	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises:

The '314 Patent – Claims	The Jubin References
a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	• The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. said wireless network, a first converter implementing a process to convert said data packet to a format used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second network; and a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via

The '314 Patent – Claims	The Jubin References
	an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):  Fig. 4. Packet radio network in the Internet.

The '314 Patent – Claims	The Jubin References
	"The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23. "[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a

The '314 Patent – Claims	The Jubin References
	strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same

The '314 Patent – Claims	The Jubin References
	time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so	"Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the

The '314 Patent – Claims	The Jubin References
that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '314 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	The Jubin References
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25.

The '471 Patent – Claims	The Jubin References
	"We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one

The '471 Patent – Claims	The Jubin References
	(referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet

The '471 Patent – Claims	The Jubin References
a client wireless communication, maintaining a send/receive data buffer in digital memory, and	provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '471 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '471 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '471 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25.

The '471 Patent – Claims	The Jubin References
	"We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one

The '471 Patent – Claims	The Jubin References
	(referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '471 Patent – Claims	The Jubin References
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '471 Patent – Claims	The Jubin References
	 Fig. 2. Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '471 Patent – Claims	The Jubin References
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated

The '471 Patent – Claims	The Jubin References
	automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier

The '471 Patent – Claims	The Jubin References
	tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
12. A method as recited in claim 11, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
14. A method for providing wireless network communication comprising the steps of: a server process including a data	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21.

The '471 Patent – Claims	The Jubin References
packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. 	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '471 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '471 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '471 Patent – Claims	The Jubin References
	 Fig. 2. Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

"After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25.

The '471 Patent – Claims	The Jubin References
	"We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one

The '471 Patent – Claims	The Jubin References
	(referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a

The '471 Patent – Claims	The Jubin References
that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '471 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '471 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '471 Patent – Claims	The Jubin References
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. 	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '471 Patent – Claims	The Jubin References
	 Fig. 2. Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

	observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table.

The '471 Patent – Claims	The Jubin References
second node link tree when said comparison meets predetermined conditions.	These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '471 Patent – Claims	The Jubin References
logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host

The '471 Patent – Claims	The Jubin References
	computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. The '471 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '471 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '471 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. 32. A wireless system as recited in claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table.

The '471 Patent – Claims	The Jubin References
tree when said comparison meets predetermined conditions.	These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host

The '471 Patent – Claims	The Jubin References
	computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

The '471 Patent – Claims	The Jubin References
	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '471 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '471 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

	observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '471 Patent – Claims	The Jubin References
when said comparison meets at least one of several predetermined conditions.	These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24.

The '471 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications

The '471 Patent – Claims	The Jubin References
modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA

send the optimized transmission path for each of the plurality of client nodes to the respective client node.	[packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the

The '471 Patent – Claims	The Jubin References
	LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	The Jubin References
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and

The '496 Patent – Claims	The Jubin References
	application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23.

The '496 Patent – Claims	The Jubin References
	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the

The '496 Patent – Claims	The Jubin References
	PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it

	PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium,

The '496 Patent – Claims	The Jubin References
communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and

The '496 Patent – Claims	The Jubin References
	terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M

The '496 Patent – Claims	The Jubin References
	• as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." 	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF

The '496 Patent – Claims	The Jubin References
	subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

The '496 Patent – Claims	The Jubin References
	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 Fig. 2. Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

Jubin 1985 at 88.
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF

The '496 Patent – Claims	The Jubin References
	subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M

The '496 Patent – Claims	The Jubin References
	• as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M

The '496 Patent – Claims	The Jubin References
	• as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. Fig. 5:

Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF

The '496 Patent – Claims	The Jubin References
	subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

The '496 Patent – Claims	The Jubin References
	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
23. A wireless network system as recited in claim 21, wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	The Jubin References
already in said second node link tree.	
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and

The '496 Patent – Claims	The Jubin References
	application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M

The '496 Patent – Claims	The Jubin References
	• as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21.

The '496 Patent – Claims	The Jubin References
the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required

The '496 Patent – Claims	The Jubin References
	protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes,	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. Fig. 5:

	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the

The '496 Patent – Claims	The Jubin References
	end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

Fig. 5. Typical tier table for PR *N*.

"The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24.

"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23.

"Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet

The '496 Patent – Claims	The Jubin References
	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M

The '496 Patent – Claims	The Jubin References
	• as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises:

Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a

The '496 Patent – Claims	The Jubin References
	strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same

The '496 Patent – Claims	The Jubin References
	time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

	network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish

The '496 Patent – Claims	The Jubin References
	to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:

The '496 Patent – Claims	The Jubin References
	 **Fig. 2.** Small packet radio network. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

	observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "The network information is stored in three tables: • neighbor table • tier table • device table.

The '496 Patent – Claims	The Jubin References
when said comparison meets at least one of several predetermined conditions.	These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "The goal of the tier table is always to maintain the "best" information about how to get to a destination packet radio. The "best" route is currently defined as the shortest route with good connectivity on each hop. Therefore, the tier table is updated only when certain conditions are met. Let us consider that N has received a PROP from M, and examine the conditions for which N updates its tier table, where the update for any given destination PR consists of storing: • as the next PR enroute: M • as the tier: M's reported tier, with respect to the destination PR, incremented by one (referred to as 'T' below). A necessary condition is that M be a bidirectionally good neighbor of N. In addition to the good neighborliness, any one of the following conditions must be met for N to update its tier table: • There is no stored tier data for that destination PR. • The prospective new tier ('T') is strictly less than the M is the same PR that is already stored as the next PR. When the link quality to a neighboring PR (say the link from PR N to PR M) becomes "bad," all routes in N's tier table for which the neighbor PR M is the next PR in the route are also set bad. This means that M can no longer provide a reliable way for N to send packets to a destination PR, and a new next PR should be chosen, and thus a new, good route can be formed even if it is longer than the old, bad one. Just as good tier data are spread via PROPs, the news of bad tier data is also spread via PROPs. PR N will include the news in its PROP that it can no longer provide a route to the destination PRs that it reached via M." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic reconfiguration capability." Jubin and Tornow at 24-25. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	The Jubin References
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on

The '496 Patent – Claims	The Jubin References
	the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

The '496 Patent – Claims	The Jubin References
	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes;	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. Fig. 5:

	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23.
42. A server for use in a wireless network system including a plurality of clients each including a client	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21.

The '496 Patent – Claims	The Jubin References
controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on

The '496 Patent – Claims	The Jubin References
	the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Figure 4 (Jubin and Tornow at 23):

	 Fig. 4. Packet radio network in the Internet. "The current network protocols are designed to support 138 entities, which can be any combination of PRs and attached devices, in a single network." Jubin and Tornow at 23.

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
maintaining a client link tree having client link entries representing each of the plurality of clients, and	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. "The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23.

The '496 Patent – Claims	The Jubin References
	"The network information is stored in three tables: • neighbor table • tier table • device table. These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes." Jubin and Tornow at 23. "[W]hen PR L is first powered up, it does not know anything about the network so its PROP simply announces its existence. The PROP is received by all neighboring radios (those in direct connectivity with L). The set of radios that hear the PROP note the event in their neighbor tables. Similarly, PR L will hear the periodic PROPs of its neighboring PRs and will start to build its own neighbor table. Once PR L begins participating in the network by passing data, the data packets are used in addition to the PROPs to maintain the neighbor table." Jubin and Tornow at 24. "This neighbor table, then, represents a PR's accumulated knowledge about all the PRs that are one hop away." Jubin and Tornow at 24. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24.

The '496 Patent – Claims	The Jubin References
	"[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. "The goal of the tier table is always to maintain the 'best' information about how to get to a destination packet radio. The 'best' route is currently defined as the shortest route with good connectivity on each hop." Jubin and Tornow at 24. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior. The Network Monitor is currently defined as an optional component of the network because it does not contribute in any way to the management of the network." Jubin and Tornow at 23. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88.

The '496 Patent – Claims	The Jubin References
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"In 1973, the Defense Advanced Research Projects Agency (DARPA) initiated research on the feasibility of using packet switched, store-and-forward radio communications to provide reliable computer communications." Jubin and Tornow at 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communications medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin and Tornow at 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users[; • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin and Tornow at 22. "[The Low-cost Packet Radio (LPR)] consists of both digital and RF subsystems… The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin and Tornow at 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface. Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on

The '496 Patent – Claims	The Jubin References
	the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet. A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR. The NIU performs the necessary host-to-host and terminal specific protocols. The PRNET can also be accessed from other networks via an Internet gateway." Jubin and Tornow at 22-23. Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	"[A] typical network may be composed of 50 packet radios, many of which have attached devices and some of which serve only as repeaters. Multiple packet radio networks operating on different frequencies may be interconnected via Internet gateways to support applications which require larger networks." Jubin and Tornow at 23. "[A]ll packet radios know of all devices and to which packet radios the devices are attached." Jubin and Tornow at 25. "If a device is moved from one PR to another, or if it goes down, its new status is made known to the network." Jubin and Tornow at 25. "In addition, the PRNET offers generic logical addressing. Generic addressing allows a device to request service from any other device in a general category, e.g., any name server or any gateway." Jubin and Tornow at 25. "In general, a PRNET consists of many PRs that are not all within line-of-sight of each other, and packets must traverse multiple hops to reach their destination." Jubin and Tornow at 22. Fig. 2:  **Fig. 2.** Small packet radio network.

The '496 Patent – Claims	The Jubin References
	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin and Tornow at 22. "As a general rule, packets are handled first-in first-out (FIFO). However, there are two exceptions to the FIFO rule. The first exception is a result of the pacing protocol described in the preceding section. Pacing can slow the rate of forwarding to one neighbor PR compared to the rate to another neighbor PR. Therefore, a packet j headed in a "fast" direction and therefore ready to go, in the pacing sense, is transmitted before one i headed in a "slow" direction and therefore not ready to go, even if i arrived before j. There is, however, a single radio transmit queue, so that, when several packets are ready to go at the same time, they will be transmitted FIFO, that is, i before j. The second exception to the FIFO rule is that received packets are not always entered at the tail of the radio transmit queue. The purpose of this exception is to overcome the inherent unfairness that may exist among various receive links. Consider in Fig. 8 three streams of packets merging at one PR (X), all going to the same neighbor PR (V): one stream is coming over a weak radio link from PR A, another is coming over a strong radio link PR B, and the last is coming over the practically error-free wire interface from device C. With straight FIFO queuing, the wire interface stream would monopolize PR X's buffer and transmission resources, and the weak radio link would not get its share. Furthermore, the pacing protocol would provide positive feedback to further exacerbate the situation." Jubin and Tornow at 28. "Packet radio networking technology applies the packet switching class of

The '496 Patent – Claims	The Jubin References
	communication to the broadcast radio channel in multi-hop networks." Jubin 1985 at 86. "Transmit link ratings are used to decide on which data rate to transmit traffic packets. Transmit and receive link ratings are used to give an overall bi-directional rating to a link; both link directions must be good to declare a link to be bi-directionally good." Jubin 1985 at 88. "A packet radio network, then, consists of two or more [packet radios], each one of which is within range of at least one other [packet radio], but all of which are not necessarily within range of each other. User devices … which wish to communicate with each other attach to [packet radios] via a wire interface." Jubin 1985 at 86. "Each [packet radio] transmits a control packet…" Jubin 1985 at 88. "[Packet radios] recognize the existence of new links, i.e., [packet radio]-to-[packet radio] transmission reception paths, by observing the transmitting [packet radio identification] in all received packets. They judge the quality of each link in terms of the ratio of the number of packets which the receiving [packet radio] received correctly … from the transmitting [packet radio] during a time period to the number of packets which the transmitting [packet radio] actually transmitted during the same time period." Jubin 1985 at 88. "The pacing protocol provides flow and congestion control." Jubin 1985 at 90. "Routes from each [packet radio] to all other [packet radios] in the network and their attached devices are created and maintained in a distributed manner. Each [packet radio] creates and maintains:

Exhibit B2 – Invalidity Chart for Brownrigg Family based on the Jubin References

The '496 Patent – Claims	The Jubin References
	- a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "The routing tables are maintained as follows. Every PR periodically transmits in a control packet (the packet which contains the neighbor data) its list of distant PR IDs, each with the route length to it and with its list of attached device IDs. Upon receipt of such a control packet…a PR extracts each distant PR ID with the route length and considers updating the corresponding entry in its distant PR table." Jubin 1985 at 88. "If a PR…which has forwarded a packet does not receive an acknowledgement within a certain interval…it…retransmits the packet." Jubin 1985 at 90.
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	"The PRNET features fully distributed network management. Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination." Jubin and Tornow at 23. "[U]ltimately every radio knows its distance in tiers from any prospective destination [packet radio] and which [packet radio] is the next [packet radio] enroute to that destination [packet radio]." Jubin and Tornow at 24. Fig. 5:

	radio] creates and maintains: - a table of the device IDs attached to it; - a table of all distant device IDs, each with the ID of the (distant) PR to which it is attached; - a table of distant [packet radio] IDs each with the ID of the next [packet radio] in the route to it, the length of the route, i.e., the number of links to be traversed to reach it." Jubin 1985 at 88. "Routing in the PRNET is done by having each PR maintain knowledge of the best PR to forward packets to every prospective destination. This is similar to the early ARPANET routing algorithm [11]. Each PR that receives PR L's PROP notes that it is only one radio hop away, so it is at 'tier 1' with respect to PR L, and includes this information about the network topology in its next PROP. Still other PRs hear the PROPs broadcast by the PRs which are at tier 1 with respect to L, note that they are one hop away from the PRs from which the PROP was received, and therefore at tier 2 with respect to PR L (which emitted the original PROP). These second-tier PRs, in turn, relay this information out another tier in the PROPs, and so on." Jubin and Tornow at 24. "After a PR (say PR l in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. As long as the PR is powered up, it will broadcast a Packet Radio Organization Packet (PROP) every 7.5 s, announcing its existence and information about the network topology from its perspective." Jubin and Tornow at 24. "Information gathered from the headers of data packets is also used to update the tier tables. Under heavy traffic loads, this greatly improves the network's responsiveness to a rapidly changing topology, and contributes significantly to the PRNET's automatic

The '496 Patent – Claims	The Jubin References
	reconfiguration capability." Jubin and Tornow at 24-25. "We have described the algorithms and illustrated how the PR NET system (i.e., the LPRs along with their attached devices) provides highly reliable network transport and datagram service, by dynamically determining optimal routes, effectively controlling congestion, and fairly allocating the channel in the face of changing link conditions, mobility, and varying traffic loads." Jubin and Tornow at 32.

said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it

The '516 Patent – Claims	Network Analysis References
	does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each

The '516 Patent – Claims	Network Analysis References
	path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973

The '516 Patent – Claims	Network Analysis References
transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II

The '516 Patent – Claims	Network Analysis References
	Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '516 Patent – Claims	Network Analysis References
	sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	The NAC references provide stations with gateway functions to a point-to-point network, such as ARPANET, which would inherently involve the TCP/IP protocol (at least as of 1982). At a minimum, it would have been obvious to use TCP/IP in the point-to-point protocol in order to provide a well-known and reliable protocol.
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	"In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." NAC Dec. 1974, § 10.1. "Stations Among the stations' functional capabilities are: a. A directory of terminals and repeaters in its region. b. Operations necessary to convert packets from the Packet Radio System into packets used in the point-to-point network and conversely. c. Storage buffers for packets received from terminals and for packets to be

The '516 Patent – Claims	Network Analysis References
	transmitted to terminals. d. Storage for character position information for active terminals which do not have this capability. e. Accounting capabilities. f. Capabilities related to routing, flow control, and network management." NAC Dec. 1974, § 10.2.1. *See also* NAC Dec. 1973 at §§ 9-10. *See also* NAC Jun. 1974 at pp. 7.1-7.52 (discussing packet handling in the packet radio network having hierarchical routing); 7.69-70 (discussing labeling and discovery of creation of network topology ("connectivity matrix")). "The network model we examine contains a large number of nodes using random transmission schemes and omnidirectional antennas. The network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional capabilities such as gateway, global control, global initialization, accounting, and directory functions, is called a station." Gitman at 927. "Typically, a radio network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional processing capabilities such as control, initialization, and accounting is called a station." Hahn at 42.
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol	"type of data associated with the packet" "Once all the repeaters have been labeled, each data packet sent by the central site

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '516 Patent – Claims	Network Analysis References
network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and	can contain the label of the repeater to which the station has been assigned. The packet must also contain a pointer indicating the current field in the label. When a packet arrives at a repeater, the packet label's current field and the repeater label's corresponding field are checked for a match. II they match, then the repeater either decrements or increments the current field indicator, depending on whether the packet is being directed to or from the station, and forwards the packet." Hahn at 44.
wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	"In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." NAC Dec. 1974, § 10.1. "Stations Among the stations' functional capabilities are: a. A directory of terminals and repeaters in its region. b. Operations necessary to convert packets from the Packet Radio System into packets used in the point-to-point network and conversely. c. Storage buffers for packets received from terminals and for packets to be transmitted to terminals. d. Storage for character position information for active terminals which do not have this capability. e. Accounting capabilities. f. Capabilities related to routing, flow control, and network management." NAC Dec. 1974, § 10.2.1.

	of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional capabilities such as gateway, global control, global initialization, accounting, and directory functions, is called a station." Gitman at 927. "Typically, a radio network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional processing capabilities such as control, initialization, and accounting is called a station." Hahn at 42.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL

The '314 Patent – Claims	Network Analysis References
	indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a

The '314 Patent – Claims	Network Analysis References
upgrade the selected transmission path in response to a request from at least one of said second nodes.	hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it

The '314 Patent – Claims	Network Analysis References
	determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater.

The '314 Patent – Claims	Network Analysis References
	Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
4. The '314 Patent – Claims	Network Analysis References
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I

The '314 Patent – Claims	Network Analysis References
	Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central

The '314 Patent – Claims	Network Analysis References
	site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
wherein said digital controller changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. …

The '471 Patent – Claims	Network Analysis References
	Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up

The '471 Patent – Claims	Network Analysis References
	its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps:

The '471 Patent – Claims	Network Analysis References
	STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of

	the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages

The '471 Patent – Claims	Network Analysis References
	are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing

The '471 Patent – Claims	Network Analysis References
	information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus

The '471 Patent – Claims	Network Analysis References
	reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the

The '471 Patent – Claims	Network Analysis References
	flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930.

The '471 Patent – Claims	Network Analysis References
	"In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '471 Patent – Claims	Network Analysis References
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary

The '471 Patent – Claims	Network Analysis References
	skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." NAC Dec. 1974, § 10.1.

The '471 Patent – Claims	Network Analysis References
	 Figure 10.1: Packet Radio System "In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting

The '471 Patent – Claims	Network Analysis References
	unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." NAC Dec. 1974, § 10.1.

The '471 Patent – Claims	Network Analysis References
providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	 Figure 10.1: Packet Radio System "In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." NAC Dec. 1974, § 10.1. *See also* NAC Dec. 1973 at §§ 9-10. *See also* NAC Jun. 1974 at pp. 7.1-7.52 (discussing packet handling in the packet radio network having hierarchical routing); 7.69-70 (discussing labeling and discovery of creation of network topology ("connectivity matrix")).

The '471 Patent – Claims	Network Analysis References
	"The network model we examine contains a large number of nodes using random transmission schemes and omnidirectional antennas. The network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional capabilities such as gateway, global control, global initialization, accounting, and directory functions, is called a station." Gitman at 927. "Typically, a radio network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional processing capabilities such as control, initialization, and accounting is called a station." Hahn at 42. "In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." NAC Dec. 1974, § 10.1. "Repeaters Functional capabilities for repeaters include: a . Calculating packet checksum. b. Packet storage and retransmission. c. Capabilities by which a station can determine whether a particular repeater (or any repeater in a particular area) is operative or dead. d. Capabilities 1, 3, and 4 of terminals. e. Capabilities, dependent on the routing strategy, for calculating the most efficient next repeater on a transmission path to a station or to a terminal. Stations

The '471 Patent – Claims	Network Analysis References
	Among the stations' functional capabilities are: a. A directory of terminals and repeaters in its region. b. Operations necessary to convert packets from the Packet Radio System into packets used in the point-to-point network and conversely. c. Storage buffers for packets received from terminals and for packets to be transmitted to terminals. d. Storage for character position information for active terminals which do not have this capability. e. Accounting capabilities. f. Capabilities related to routing, flow control, and network management." NAC Dec. 1974, § 10.2.1. *See also* NAC Dec. 1973 at §§ 9-10. *See also* NAC Jun. 1974 at pp. 7.1-7.52 (discussing packet handling in the packet radio network having hierarchical routing); 7.69-70 (discussing labeling and discovery of creation of network topology ("connectivity matrix")). The '471 Patent – Claims	Network Analysis References
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

The '471 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

The '471 Patent – Claims	Network Analysis References
	implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8.

The '471 Patent – Claims	Network Analysis References
	"The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater.

The '471 Patent – Claims	Network Analysis References
	… Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. 	exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical

	algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
