7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets

The '471 Patent – Claims	Dynamic Source Routing References
	that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the

The '471 Patent – Claims	Dynamic Source Routing References
	existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet."

The '471 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these

The '471 Patent – Claims	Dynamic Source Routing References
said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Mobile Computing at 168.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main

The '471 Patent – Claims	Dynamic Source Routing References
sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if

The '471 Patent – Claims	Dynamic Source Routing References
	one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23]

The '471 Patent – Claims	Dynamic Source Routing References
	could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the

The '471 Patent – Claims	Dynamic Source Routing References
	target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet."

The '471 Patent – Claims	Dynamic Source Routing References
	Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160.

The '471 Patent – Claims	Dynamic Source Routing References
	"[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be

The '471 Patent – Claims	Dynamic Source Routing References
	shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178.

The '471 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-

The '471 Patent – Claims	Dynamic Source Routing References
	known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily

The '471 Patent – Claims	Dynamic Source Routing References
	broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. The '471 Patent – Claims	Dynamic Source Routing References
	and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet

The '471 Patent – Claims	Dynamic Source Routing References
	should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the

The '471 Patent – Claims	Dynamic Source Routing References
	packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular,

The '471 Patent – Claims	Dynamic Source Routing References
	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in

The '471 Patent – Claims	Dynamic Source Routing References
	promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the

	next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
12. A method as recited in claim 11, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these

	optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Mobile Computing at 168.
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1.

The '471 Patent – Claims	Dynamic Source Routing References
	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4.

The '471 Patent – Claims	Dynamic Source Routing References
	"[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the

The '471 Patent – Claims	Dynamic Source Routing References
	target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular,

The '471 Patent – Claims	Dynamic Source Routing References
	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153.

The '471 Patent – Claims	Dynamic Source Routing References
	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other

The '471 Patent – Claims	Dynamic Source Routing References
	hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3.

The '471 Patent – Claims	Dynamic Source Routing References
	"As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4.

Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular,

The '471 Patent – Claims	Dynamic Source Routing References
	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches."

Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this

The '471 Patent – Claims	Dynamic Source Routing References
	packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

The '471 Patent – Claims	Dynamic Source Routing References
sends the optimized transmission path for each of the clients to the respective clients.	
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '471 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9.

The '471 Patent – Claims	Dynamic Source Routing References
	"The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. 	infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Mobile Computing at 168.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3

The '471 Patent – Claims	Dynamic Source Routing References
	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

The '471 Patent – Claims	Dynamic Source Routing References
	"Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the

The '471 Patent – Claims	Dynamic Source Routing References
	target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '471 Patent – Claims	Dynamic Source Routing References
	"This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized

The '471 Patent – Claims	Dynamic Source Routing References
	administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '471 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.

The '471 Patent – Claims	Dynamic Source Routing References
	"[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167.

The '471 Patent – Claims	Dynamic Source Routing References
	"Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is

The '471 Patent – Claims	Dynamic Source Routing References
	cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in

The '471 Patent – Claims	Dynamic Source Routing References
	its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then

The '471 Patent – Claims	Dynamic Source Routing References
	sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this

The '471 Patent – Claims	Dynamic Source Routing References
node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5.

The '471 Patent – Claims	Dynamic Source Routing References
	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11

The '471 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5.

The '471 Patent – Claims	Dynamic Source Routing References
	"We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the

The '471 Patent – Claims	Dynamic Source Routing References
	route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165.

The '471 Patent – Claims	Dynamic Source Routing References
	"[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere

The '471 Patent – Claims	Dynamic Source Routing References
	in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '471 Patent – Claims	Dynamic Source Routing References
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's

The '471 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a

The '471 Patent – Claims	Dynamic Source Routing References
	packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '471 Patent – Claims	Dynamic Source Routing References
	is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this

The '471 Patent – Claims	Dynamic Source Routing References
	host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be

The '471 Patent – Claims	Dynamic Source Routing References
	shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to

The '471 Patent – Claims	Dynamic Source Routing References
one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.

The '471 Patent – Claims	Dynamic Source Routing References
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2.

The '471 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the

The '471 Patent – Claims	Dynamic Source Routing References
	target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160.

The '471 Patent – Claims	Dynamic Source Routing References
	"While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '471 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned,

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4.

The '471 Patent – Claims	Dynamic Source Routing References
	"Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be

The '471 Patent – Claims	Dynamic Source Routing References
	small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach

The '471 Patent – Claims	Dynamic Source Routing References
	C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163.

The '471 Patent – Claims	Dynamic Source Routing References
	"This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
the first node process further comprises maintaining a second node link tree having second node link entries.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to

The '471 Patent – Claims	Dynamic Source Routing References
	each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is

The '471 Patent – Claims	Dynamic Source Routing References
	desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163.

The '471 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
32. A wireless system as recited in	"Mobile hosts should cache routes discovered in this way for use in sending future

The '471 Patent – Claims	Dynamic Source Routing References
claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link tree when said comparison meets predetermined conditions.	packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. 33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. 	earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other

The '471 Patent – Claims	Dynamic Source Routing References
	packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161.

The '471 Patent – Claims	Dynamic Source Routing References
	"As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its

The '471 Patent – Claims	Dynamic Source Routing References
	cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '471 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's

The '471 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
maintaining a second node link tree having second node link entries at the first node.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other

The '471 Patent – Claims	Dynamic Source Routing References
	mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the

The '471 Patent – Claims	Dynamic Source Routing References
	existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet."

The '471 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

The '471 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. The '471 Patent – Claims	Dynamic Source Routing References
	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17.

The '471 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc

The '471 Patent – Claims	Dynamic Source Routing References
	networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153.

The '471 Patent – Claims	Dynamic Source Routing References
	"[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23]

The '471 Patent – Claims	Dynamic Source Routing References
	could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original

The '471 Patent – Claims	Dynamic Source Routing References
	sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of

The '471 Patent – Claims	Dynamic Source Routing References
send the optimized transmission path for each of the plurality of client nodes to the respective client node.	use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request

The '471 Patent – Claims	Dynamic Source Routing References
	does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '471 Patent – Claims	Dynamic Source Routing References
	"Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be

The '471 Patent – Claims	Dynamic Source Routing References
	small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to

The '471 Patent – Claims	Dynamic Source Routing References
	also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	Dynamic Source Routing References
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson

The '496 Patent – Claims	Dynamic Source Routing References
	1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. The '496 Patent – Claims	Dynamic Source Routing References
	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route

The '496 Patent – Claims	Dynamic Source Routing References
	discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein the server process is configured to:	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	"[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. 	earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option."

The '496 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166.

The '496 Patent – Claims	Dynamic Source Routing References
	"An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

The '496 Patent – Claims	Dynamic Source Routing References
	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc

The '496 Patent – Claims	Dynamic Source Routing References
	networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '496 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. 	also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then

The '496 Patent – Claims	Dynamic Source Routing References
	sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11.

The '496 Patent – Claims	Dynamic Source Routing References
	"A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. 7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3

The '496 Patent – Claims	Dynamic Source Routing References
	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
	"Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the

The '496 Patent – Claims	Dynamic Source Routing References
	target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized

The '496 Patent – Claims	Dynamic Source Routing References
	administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.

The '496 Patent – Claims	Dynamic Source Routing References
	"[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167.

The '496 Patent – Claims	Dynamic Source Routing References
	"Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is

The '496 Patent – Claims	Dynamic Source Routing References
	received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the

	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route

The '496 Patent – Claims	Dynamic Source Routing References
	cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in

The '496 Patent – Claims	Dynamic Source Routing References
	its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then

	packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162.

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in

The '496 Patent – Claims	Dynamic Source Routing References
	promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. The '496 Patent – Claims	Dynamic Source Routing References
	future replies from C, D, and E that include this hop from their caches." Mobile Computing at 168.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information

The '496 Patent – Claims	Dynamic Source Routing References
	from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each

The '496 Patent – Claims	Dynamic Source Routing References
	forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
11. A method for providing wireless network communication comprising:	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support

The '496 Patent – Claims	Dynamic Source Routing References
utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an

The '496 Patent – Claims	Dynamic Source Routing References
	earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '496 Patent – Claims	Dynamic Source Routing References
	is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route

The '496 Patent – Claims	Dynamic Source Routing References
	in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is

The '496 Patent – Claims	Dynamic Source Routing References
	desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the

The '496 Patent – Claims	Dynamic Source Routing References
	interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining]

The '496 Patent – Claims	Dynamic Source Routing References
	the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3.

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route

The '496 Patent – Claims	Dynamic Source Routing References
	cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this

The '496 Patent – Claims	Dynamic Source Routing References
	packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '496 Patent – Claims	Dynamic Source Routing References
	is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58.

The '496 Patent – Claims	Dynamic Source Routing References
	"The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further includes maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process:	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may

The '496 Patent – Claims	Dynamic Source Routing References
	infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166.

The '496 Patent – Claims	Dynamic Source Routing References
	"An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4.

The '496 Patent – Claims	Dynamic Source Routing References
clients.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Mobile Computing at 162-63.

The '496 Patent – Claims	Dynamic Source Routing References
	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other

The '496 Patent – Claims	Dynamic Source Routing References
	hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Mobile Computing at 168.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future

	packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme,

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route

The '496 Patent – Claims	Dynamic Source Routing References
	discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing

The '496 Patent – Claims	Dynamic Source Routing References
	references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a

The '496 Patent – Claims	Dynamic Source Routing References
	suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17.

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc

The '496 Patent – Claims	Dynamic Source Routing References
	networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. 	"[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23]

The '496 Patent – Claims	Dynamic Source Routing References
	could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original

The '496 Patent – Claims	Dynamic Source Routing References
	sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of

The '496 Patent – Claims	Dynamic Source Routing References
	use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
17. A method for providing wireless network communication comprising the steps of: a server process including a data	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract.

The '496 Patent – Claims	Dynamic Source Routing References
packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the

The '496 Patent – Claims	Dynamic Source Routing References
	routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the

The '496 Patent – Claims	Dynamic Source Routing References
	destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and

The '496 Patent – Claims	Dynamic Source Routing References
	use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to

The '496 Patent – Claims	Dynamic Source Routing References
	accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178.

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to,

The '496 Patent – Claims	Dynamic Source Routing References
	e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its

The '496 Patent – Claims	Dynamic Source Routing References
	cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's

The '496 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a

	packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other

The '496 Patent – Claims	Dynamic Source Routing References
	mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the

The '496 Patent – Claims	Dynamic Source Routing References
	existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. 	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request

The '496 Patent – Claims	Dynamic Source Routing References
	does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a

The '496 Patent – Claims	Dynamic Source Routing References
	mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts

The '496 Patent – Claims	Dynamic Source Routing References
	operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is

The '496 Patent – Claims	Dynamic Source Routing References
	desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will

The '496 Patent – Claims	Dynamic Source Routing References
link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Mobile Computing at 168.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded

The '496 Patent – Claims	Dynamic Source Routing References
	in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to

The '496 Patent – Claims	Dynamic Source Routing References
	another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159.

The '496 Patent – Claims	Dynamic Source Routing References
	"We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each

The '496 Patent – Claims	Dynamic Source Routing References
first node through at least one of the remainder of said plurality of second nodes,	other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '496 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is

The '496 Patent – Claims	Dynamic Source Routing References
	received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158.

The '496 Patent – Claims	Dynamic Source Routing References
	"Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc

The '496 Patent – Claims	Dynamic Source Routing References
	network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts

The '496 Patent – Claims	Dynamic Source Routing References
	operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other

"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and

The '496 Patent – Claims	Dynamic Source Routing References
	use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178.

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to,

The '496 Patent – Claims	Dynamic Source Routing References
	e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its

The '496 Patent – Claims	Dynamic Source Routing References
	cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's

The '496 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a

The '496 Patent – Claims	Dynamic Source Routing References
	packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network;	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1.

	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the

In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other

The '496 Patent – Claims	Dynamic Source Routing References
	hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in

The '496 Patent – Claims	Dynamic Source Routing References
	its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to

The '496 Patent – Claims	Dynamic Source Routing References
	accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic;	It would have been obvious to implement authentication of clients and maintenance of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. Mobile Computing at 168.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business

The '496 Patent – Claims	Dynamic Source Routing References
performing node link tree housekeeping functions,	associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5.

The '496 Patent – Claims	Dynamic Source Routing References
	"We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the

The '496 Patent – Claims	Dynamic Source Routing References
	route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165.

The '496 Patent – Claims	Dynamic Source Routing References
	"[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere

The '496 Patent – Claims	Dynamic Source Routing References
	in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '496 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '496 Patent – Claims	Dynamic Source Routing References
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes,	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record

The '496 Patent – Claims	Dynamic Source Routing References
	from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular,

The '496 Patent – Claims	Dynamic Source Routing References
	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches."

The '496 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 166-67. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes,	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References

	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5.

The '496 Patent – Claims	Dynamic Source Routing References
	"We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '496 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '496 Patent – Claims	Dynamic Source Routing References
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's

The '496 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that

The '496 Patent – Claims	Dynamic Source Routing References
	destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the

The '496 Patent – Claims	Dynamic Source Routing References
	interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in

The '496 Patent – Claims	Dynamic Source Routing References
	one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58.

The '496 Patent – Claims	Dynamic Source Routing References
	"If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
remainder of said plurality of second nodes,	"[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in

The '496 Patent – Claims	Dynamic Source Routing References
	the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum

The '496 Patent – Claims	Dynamic Source Routing References
	allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as

The '496 Patent – Claims	Dynamic Source Routing References
	a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record

The '496 Patent – Claims	Dynamic Source Routing References
	from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business

The '496 Patent – Claims	Dynamic Source Routing References
	associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '496 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2.

The '496 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the

The '496 Patent – Claims	Dynamic Source Routing References
	target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160.

The '496 Patent – Claims	Dynamic Source Routing References
	"While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned,

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc

The '496 Patent – Claims	Dynamic Source Routing References
	network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts

The '496 Patent – Claims	Dynamic Source Routing References
	operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned

	to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17.

The '496 Patent – Claims	Dynamic Source Routing References
	"In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7.

Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

The '496 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply

The '496 Patent – Claims	Dynamic Source Routing References
	is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
	"As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular,

The '496 Patent – Claims	Dynamic Source Routing References
	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches."

The '496 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
	"When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the

The '496 Patent – Claims	Dynamic Source Routing References
	target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located

The '496 Patent – Claims	Dynamic Source Routing References
	at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson

Mobile Computing at 168.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned

The '496 Patent – Claims	Dynamic Source Routing References
	to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet,

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

The '496 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply

The '496 Patent – Claims	Dynamic Source Routing References
	is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
through at least one other client node; determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and maintain a client link tree having client link entries representing each of the plurality of client nodes.	"As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '496 Patent – Claims	Dynamic Source Routing References
	does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has

The '496 Patent – Claims	Dynamic Source Routing References
	earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract.

The '496 Patent – Claims	Dynamic Source Routing References
said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	"Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the

The '496 Patent – Claims	Dynamic Source Routing References
	routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1.

The '496 Patent – Claims	Dynamic Source Routing References
	"[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to,

The '496 Patent – Claims	Dynamic Source Routing References
	e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its

The '496 Patent – Claims	Dynamic Source Routing References
	cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that

The '496 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's

The '496 Patent – Claims	Dynamic Source Routing References
	header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a

	earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option."

The '496 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a client link tree having client link entries representing each of the plurality of clients, and	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the

The '496 Patent – Claims	Dynamic Source Routing References
	route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162.

The '496 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. The '496 Patent – Claims	Dynamic Source Routing References
	from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7.

The '496 Patent – Claims	Dynamic Source Routing References
	"This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each

The '496 Patent – Claims	Dynamic Source Routing References
	forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63. It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
44. The server of claim 42, wherein the client link entries correspond to	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3.

The '496 Patent – Claims	Dynamic Source Routing References
the server selected transmission path between the server and the respective client.	"[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

	earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option."

The '496 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166.

The '496 Patent – Claims	Dynamic Source Routing References
	"An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

The '496 Patent – Claims	Dynamic Source Routing References
	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4.

The '496 Patent – Claims	Dynamic Source Routing References
	"To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc

The '496 Patent – Claims	Dynamic Source Routing References
	networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '496 Patent – Claims	Dynamic Source Routing References
	Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson

The '496 Patent – Claims	Dynamic Source Routing References
	1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks,

The '496 Patent – Claims	Dynamic Source Routing References
	including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme,

The '496 Patent – Claims	Dynamic Source Routing References
	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route

The '496 Patent – Claims	Dynamic Source Routing References
	cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '496 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this

The '496 Patent – Claims	Dynamic Source Routing References
	packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '496 Patent – Claims	Dynamic Source Routing References
	is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
dynamically updating a second node link tree comprising second node link	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing

The '496 Patent – Claims	Dynamic Source Routing References
entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

The '516 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '516 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge

The '516 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network. It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.

The '516 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.

The '516 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.

The '314 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '314 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an

The '314 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
4. A first node providing a gateway	"The invention features methods and apparatus for determining a route from a source

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '314 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said second network; and a second data packet receiver configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route

maintaining a send/receive data buffer in digital memory, and	with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from

The '471 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.

The '471 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to:	"FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN

The '471 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52.

The '471 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is

The '471 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

	'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5.

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	"While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to: receive information identifying the selected transmission path from each	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58.
4. A wireless network system as recited in claim 2, wherein said server	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN

Perlman at 6:6-10.
17. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58.

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

Perlman at 14:41-58.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic;	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time."

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes,	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes,	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
the second node configured to implement a second node process including: sending and receiving data packet via a second node wireless radio;	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
maintaining a send/receive data buffer in a digital memory; and	refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	Perlman at 14:41-58.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
server node controller implementing a server process, said server process configured to:	244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route

Exhibit B6 – Invalidity Chart for Brownrigg Family based on U.S. Patent No. 5,323,394 (Perlman)

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
server selected transmission path for each of the plurality of client nodes to the respective client node; and	to the source end system." Perlman at 6:6-10.
maintain a client link tree having client link entries representing each of the plurality of client nodes.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
packets via said client radio modem,	listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then,

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
maintaining a client link tree having client link entries representing each of the plurality of clients, and	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
receiving information identifying the selected transmission path from each of the plurality of clients, determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.
44. The server of claim 42, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	to the source end system." Perlman at 6:6-10.
45. A first node for use in wireless network system including a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time. However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
wherein said second node process of each of said second nodes includes	"Ordinarily, to send a message from a transmitting end system to a receiving end system on the same LAN, a header is attached to the message indicating the address

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	of the source end system and the destination end system. Thus, for example, a message transmitted from a source end system having an address X to a destination end system having an address Y has a header: Y|X Each end system on the LAN, upon receiving this message, determines if its address is Y, and if so, the end system reads the message. To send a message from a transmitting end system on a first LAN to a receiving end system on a second LAN, the sequence of LAN numbers that should be traversed to reach the second LAN is appended to the message. For example, if end system 100 has address X, and end system 102 has address Y, a message to be transmitted from end system to end system 102 would contain a header with the sequence: Y|X|L5|L3|L9 or, alternatively, the message might contain the sequence: Y|X|L5|L3|L9 either of which indicates a path from end system 102 to end system 100 (i.e., from LAN L5 to LAN L7 or LAN L3, and then to LAN L9). Schemes which use this technique are known as 'source routing bridging' schemes, and the messages containing such a sequence are known as 'source routed' messages. (Further detail on one source routing bridging scheme can be found in IEEE Proposed Standard 802.5M/D6, entitled 'Source Routing Transparent Bridge Operation', available from the IEEE Service Center, 445 Hoes Lane, P.O. Box 1331, Piscataway, N.J. 08855-1331, and incorporated herein by reference.)" Perlman at 3:33-4:5. "While the above describes the typical mechanism for routing packets in a LAN/bridge network, it does not explain how the routes are determined. This is typically accomplished by means of 'explorer' messages. When an end system seeks to

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	locate a route to another end system which is not on the same LAN, it originates an explorer message indicating the address of the desired destination, and then transmits the explorer message on the LAN. Through a procedure described below, copies of the explorer message are propagated through all of the bridges and LANs in the network, exploring every possible route through the network and collecting information about the paths followed. The explorers may also accumulate other data, such as the maximum packet size along the path followed or the 'cost' (expediency) of those paths. Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system. Once the acknowledgement is received by the source end system, communications can begin using the source routing scheme described above." Perlman 5:53-12.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"The invention features methods and apparatus for determining a route from a source end system to a destination end system through a network comprised of LANs and bridges connecting the LANs." Perlman at 1:49-52. "FIG. 5F illustrates the procedure by which the root bridge deals with LAN number refresh messages from other designated bridges. After receiving 240 the refresh message, the root bridge determines 242 whether its database associates the LAN number listed in the refresh message (field 284, FIG. 6C) with the bridge and port listed in the refresh message (fields 280 and 282, FIG. 6C). If so, the root bridge resets 244 the refresh time in the corresponding entry to the current time.

The '496 Patent – Claims	U.S. Patent No. 5,323,394 (Perlman)
	However, if the refresh message and the database do not correspond, the root bridge then determines 246 whether the LAN number in the refresh message is associated with another bridge and port. If not, the root bridge updates its database by associating the bridge and port listed in the message with the LAN number indicated in the message, and then resets 244 the refresh time in the entry to the current time." Perlman at 14:41-58. It would have been obvious to implement the route discovery and management techniques of Perlman in a wireless network having the controller and modem features claimed, including the destination acting as a gateway to the internet and translating packets between the internet and wireless network.
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	"Eventually, multiple copies of the explorer packet reach the destination end system, and the destination end system is able to compare the various paths that were found, and choose the most expedient route (e.g., by selecting the route which passed through the least number of LANs, or the route with the lowest 'cost'). Then, the destination end system stores this route for use in future communications with the source end system, and transmits an acknowledgement message containing the route to the source end system." Perlman at 6:6-10.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The Network 3000 system, including the Network 3000 Server Configuration Manual (June 1992), relates to hierarchical routing in a network.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Network 3000
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with

The '516 Patent – Claims	Network 3000
received from said second network that are destined for said first network to said first network,	the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '516 Patent – Claims	Network 3000
	Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '516 Patent – Claims	Network 3000
the least amount of traffic, and the path to the gateway through the fastest clients.	optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in

The '516 Patent – Claims	Network 3000
data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links."

The '516 Patent – Claims	Network 3000
network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '516 Patent – Claims	Network 3000
	"The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in

The '516 Patent – Claims	Network 3000
clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5.

The '516 Patent – Claims	Network 3000
the server can be through one or more other clients of the first network.	"The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Network 3000
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed

The '314 Patent – Claims	Network 3000
	periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.

The '314 Patent – Claims	Network 3000
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said selected path to said	"The Time Synchronization/Node Routing Table (TS/NRT) combined message

The '314 Patent – Claims	Network 3000
first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately

The '314 Patent – Claims	Network 3000
second network; and a second data packet receiver configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in

The '314 Patent – Claims	Network 3000
	a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group consisting essentially of the path to first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic,	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the

The '314 Patent – Claims	Network 3000
and the path to the first node through the fastest second nodes.	manner claimed so as to develop an accurate assessment of network conditions.
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising: a client node radio modem; and a client node controller; said client node controller implementing a process including receiving and transmitting data packets via said client modem;	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence

The '314 Patent – Claims	Network 3000
	of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '314 Patent – Claims	Network 3000
selecting a radio transmission path to said server node that is one of a direct link to said server node and an indirect link to said server node through at least one other client node;	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '314 Patent – Claims	Network 3000
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network; a digital controller coupled to said	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '314 Patent – Claims	Network 3000
radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '314 Patent – Claims	Network 3000
	"Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
wherein said digital controller	"The Time Synchronization/Node Routing Table (TS/NRT) combined message

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '314 Patent – Claims	Network 3000
changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
13. A first node as recited in claim 12, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller converts data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '314 Patent – Claims	Network 3000
14. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver implementing a process to receive a data packet from a second node of said wireless network, a first converter implementing a process to convert said data packet to a format used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second network; and a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at

The '314 Patent – Claims	Network 3000
	§ 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
a controller implementing a process	"The Time Synchronization/Node Routing Table (TS/NRT) combined message

The '314 Patent – Claims	Network 3000
to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Network 3000
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed

The '471 Patent – Claims	Network 3000
	periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said server process further	"The Time Synchronization/Node Routing Table (TS/NRT) combined message

The '471 Patent – Claims	Network 3000
includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
6. A wireless network system comprising:	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message

The '471 Patent – Claims	Network 3000
	"The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
a link selection step that is one of a direct link to a server and an indirect	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
link to said server through at least one of the remainder of said plurality of clients,	recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said server process further comprises the step of maintaining a client link tree having client link	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
entries corresponding to an optimized transmission path for each of the plurality of clients, and	TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
15. A method as recited in claim 14, wherein said server process further	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message

The '471 Patent – Claims	Network 3000
node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
	"The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
	the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in

The '471 Patent – Claims	Network 3000
	the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.
19. A wireless network system as recited in claim 18 wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic;	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. 	Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to

The '471 Patent – Claims	Network 3000
	serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2.

The '471 Patent – Claims	Network 3000
	"Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.

The '471 Patent – Claims	Network 3000
second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '471 Patent – Claims	Network 3000
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network

The '471 Patent – Claims	Network 3000
	hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2.

The '471 Patent – Claims	Network 3000
	"Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
maintaining a second node link tree having second node link entries at the first node.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
35. A method as recited in claim 34, wherein said first node process further includes:	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.

The '471 Patent – Claims	Network 3000
comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no

The '471 Patent – Claims	Network 3000
receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3.

The '471 Patent – Claims	Network 3000
	"Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The '496 Patent – Claims	Network 3000
from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
not already in said client link tree.	
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully

The '496 Patent – Claims	Network 3000
	received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node."

The '496 Patent – Claims	Network 3000
	Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.

The '496 Patent – Claims	Network 3000
receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the server selected transmission path, and send information identifying the server selected transmission path for each of the clients to the respective clients.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.
9. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

The '496 Patent – Claims	Network 3000
recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	of the network map, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed

The '496 Patent – Claims	Network 3000
	periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein the server process:	"The Time Synchronization/Node Routing Table (TS/NRT) combined message

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
maintains a client link tree having client link entries representing each of the plurality of clients.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.

The '496 Patent – Claims	Network 3000
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. 	disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with

The '496 Patent – Claims	Network 3000
	the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in

Exhibit B7 – Invalidity Chart for Brownrigg Family based on Network 3000

The '496 Patent – Claims	Network 3000
provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	It would have been obvious to compares links in a client link tree to links made available during operation and update the client link tree accordingly.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	Network 3000
link tree if said client is authentic and is not already in said client link tree.	
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node	"BSAP supports a simple tree topology. As a matter of terminology, the network master computer is defined as the root of the tree. Emanating from the root is the first level of node(s) or branch. From the first level there may be a second level; and from the second a third; and so forth up to a maximum of six levels. There is no requirement for symmetry within the tree structure." Network 3000 at § 2.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links."

The '496 Patent – Claims	Network 3000
process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	Network 3000 at § A.3. "Any given node within the network (except the extremities) serves a dual purpose. It is master to the node(s) immediately below it and slave to the node immediately above it. These two relationships are defined as local because the nodes involved are adjacent to each other. Messages between a master and slave (with no intervening nodes) are defined as local messages. Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6.

The '496 Patent – Claims	Network 3000
	"The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous

The '496 Patent – Claims	Network 3000
	local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5.

Messages which must pass through one or more intervening nodes to reach their destination are defined as global messages. Figure 1 illustrates a simple network and the global and local relationships between its nodes. To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence

The '496 Patent – Claims	Network 3000
	of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2. "The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.

The '496 Patent – Claims	Network 3000
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"In addition to receiving the TS/NRT message from the Master node, a Slave node will request a TS/NRT message following an initial download, or after a power-fail recovery" Network 3000 at § 4.5. "Each slave then uses the procedure described below to construct its NRT which it then passes to each of its slaves. Both the NRT global address field and UP/DOWN mask starts off as zero (i.e. the network master's global address and UP/DOWN mask are by definition zero). As the NRT is distributed each node determines its global address and UP/DOWN mask and fills in the appropriate field in the NRT. Therefore the global .address of a node is the concatenation of the local addresses of all previous local masters that the NRT has travelled to from the network master to that node." Network 3000 at § 4.5.1. "Global data messages are those which must pass through at least one master before reaching their destination." Network 3000 at § 3.2. "Local messages are those which do not have to pass through any nodes to reach their destination." Network 3000 at § 3.2. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.

To assist you in developing your particular network configuration, Bristol Babcock has a program called NETTOP available." Network 3000 at § 2.3. "Peer to Peer is a mechanism for data transfer between nodes on the Network-3000. Peer to Peer uses the Master and Slave modules which should not be confused with the BSAP Master/Slave communication scheme. Peer to Peer allows any node to be a Peer to Peer Master and/or Slave. The determining factor is the presence or absence of the Peer to Peer Master and Slave ACCOL module(s}. A Master module is executed periodically at the request of the ACCOL task in which it is present." Network 3000 at § 4.2.

The '496 Patent – Claims	Network 3000
	"The asynchronous protocol presented here is appropriate for transparent message switching applications utilizing hard wire, telephone, and radio communication links." Network 3000 at § A.3. "Buffering failures occur when a node does not have sufficient space to accept a data message." Network 3000 at § 2.6. "The UP-ACK message is used by the master to inform the slave that it successfully received and buffered the message." Network 3000 at § 3.1. "Therefore, alarms from the local master and/or one or more slaves may be placed in a single communication buffer for transmission to the next level of the network hierarchy." Network 3000 at § 4.1. It would have been obvious for the node associated with the master computer to serve as a gateway to, e.g., the internet, so that the node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). Further, to the extent not inherent, it would have been obvious to use data buffers in the manner claimed in such a system.
receive information identifying selected transmission paths from each	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the

The '496 Patent – Claims	Network 3000
of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the manner claimed so as to develop an accurate assessment of network conditions.
determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and	"The Time Synchronization/Node Routing Table (TS/NRT) combined message enables each node in a Network 3000 configuration to know what the topology of the network is, the node's unique global address and the current date and time. The TS/NRT emanates from the Network Master Device and 'trickles' down from level to level until each node on the network has received it. There is NO application level acknowledgement to the TS/NRT message." Network 3000 at § 4.5. "The NRT is created at the Network Master Device using the NETTOP utility program. The NRT may be modified at any time when a network configuration change has occurred. Once the NRT has been altered the new NRT is distributed to all nodes in the running system." Network 3000 at § 4.5. To the extent not inherent, it would have been obvious to a person of ordinary skill to optimize the NRT based on the packets received from the downstream nodes in the

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The Layer Net reference, Bhatnagar, A. and Robertson, T., "Layer Net: A New Self-Organizing Network Protocol," MILCOM 90, 1990 IEEE Military Comm. Conf. 845 (Sept.-Oct. 1990) (Layer Net), includes descriptions relating to routing in a self-organizing network.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Layer Net Reference
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is

<u>**Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net**</u>

The '516 Patent – Claims	Layer Net Reference
second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '516 Patent – Claims	Layer Net Reference
	identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

The '516 Patent – Claims	Layer Net Reference
	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the

	known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable

The '516 Patent – Claims	Layer Net Reference
transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring

The '516 Patent – Claims	Layer Net Reference
and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then

The '516 Patent – Claims	Layer Net Reference
	search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846.

When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the

This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or

The '314 Patent – Claims	Layer Net Reference
	node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.

The '314 Patent – Claims	Layer Net Reference
	"Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree

The '314 Patent – Claims	Layer Net Reference
	by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. The '314 Patent – Claims	Layer Net Reference
	them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Layer Net Reference
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '471 Patent – Claims	Layer Net Reference
	"In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link.

The '471 Patent – Claims	Layer Net Reference
	When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. 	during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is

The '471 Patent – Claims	Layer Net Reference
	realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '471 Patent – Claims	Layer Net Reference
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of

The '471 Patent – Claims	Layer Net Reference
	available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by

	appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845.

The '471 Patent – Claims	Layer Net Reference
data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and

The '471 Patent – Claims	Layer Net Reference
	interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages.

The '471 Patent – Claims	Layer Net Reference
	When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network."

The '471 Patent – Claims	Layer Net Reference
	Layer Net at 846-47.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then

Any node can serve as the starter node." Layer Net at 845.

The '471 Patent – Claims	Layer Net Reference
implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network.

The '471 Patent – Claims	Layer Net Reference
	When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.

The '471 Patent – Claims	Layer Net Reference
	"Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '471 Patent – Claims	Layer Net Reference
	neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled

The '471 Patent – Claims	Layer Net Reference
	operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises:	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then

The '471 Patent – Claims	Layer Net Reference
logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each

The '471 Patent – Claims	Layer Net Reference
	other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846.

The '471 Patent – Claims	Layer Net Reference
	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
maintaining a second node link tree having second node link entries at the first node.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all

The '471 Patent – Claims	Layer Net Reference
	nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '471 Patent – Claims	Layer Net Reference
	When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '471 Patent – Claims	Layer Net Reference
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846.

The '471 Patent – Claims	Layer Net Reference
	"In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link.

The '471 Patent – Claims	Layer Net Reference
	When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	(which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by

The '496 Patent – Claims	Layer Net Reference
	appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to

	identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or

The '496 Patent – Claims	Layer Net Reference
	node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.

The '496 Patent – Claims	Layer Net Reference
	It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
	"In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two

When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
	It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
maintains a client link tree having client link entries representing each of the plurality of clients.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.

The '496 Patent – Claims	Layer Net Reference
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner.

The '496 Patent – Claims	Layer Net Reference
	Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
	realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845.

The '496 Patent – Claims	Layer Net Reference
	"Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its

The '496 Patent – Claims	Layer Net Reference
	neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving

The '496 Patent – Claims	Layer Net Reference
each of the clients to the respective clients.	them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages.

The '496 Patent – Claims	Layer Net Reference
	When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum

The '496 Patent – Claims	Layer Net Reference
	disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network.

The '496 Patent – Claims	Layer Net Reference
	When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node

Exhibit B8 – Invalidity Chart for Brownrigg Family based on Layer Net

The '496 Patent – Claims	Layer Net Reference
	to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn

The '496 Patent – Claims	Layer Net Reference
	the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by

The '496 Patent – Claims	Layer Net Reference
	communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then

The '496 Patent – Claims	Layer Net Reference
	search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846.

The '496 Patent – Claims	Layer Net Reference
	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.

The '496 Patent – Claims	Layer Net Reference
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. 	during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
27. In a wireless system comprising a plurality of second nodes and a first	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at

The '496 Patent – Claims	Layer Net Reference
node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting

The '496 Patent – Claims	Layer Net Reference
	from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	"Since all nodes acquire complete global topological information, they can form routing tables for sending data packets on efficient routes to all other nodes." Layer Net at 845. "All peripheral nodes transmit 'return messages' back to the starter node along the

The '496 Patent – Claims	Layer Net Reference
	tree. A node waits for a return message from all its children before transmitting, and its own return message contains all information about the tree below it and its neighbors. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network (which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by

The '496 Patent – Claims	Layer Net Reference
	communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849.
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	Layer Net Reference
determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is

The '496 Patent – Claims	Layer Net Reference
	rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846. "Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. Thus, when all the nl nodes have transmitted to the starter node, this node has the configuration of the asynchroronous tree network and the locations of all nodes in the network." Layer Net at 846. "When the starter node has received complete information about the tree network

The '496 Patent – Claims	Layer Net Reference
	(which includes information about node locations and physical neighbors of all nodes), this entire map is then transmitted down the tree to all the nodes, thus giving them complete global information." Layer Net at 846. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845. "The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is

The '496 Patent – Claims	Layer Net Reference
	present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. The efficiency of the schedule can be enhanced by permitting pairs of nodes to communicate in any free slots that may be available to them." Layer Net at 846.

The '496 Patent – Claims	Layer Net Reference
	"Changes in topology can result in an old link (or node) going down or a new link (or node,) coming up during the operation of the network. When a link goes down the previously connected nodes can no longer hear each other. This may occur if the nodes are moving away from each other. The nodes then search their routing tables for alternate paths to route their data packets and register the fact that the link no longer exists. This is also reported to other nodes in the network by appending this information with all data packets and negation messages. This information will be allowed to percolate throughout the network. The two disconnected nodes then listen to transmissions occurring during their free slots to identify their new neighbors (if any) and form one or more new links by communicating with those neighbors. Since we are following the "minimum disturbance criterion", new links are formed only when old links are broken. This formation of new links is reported to other nodes during the course of scheduled operation in a manner similar to the reporting of a broken link. When a node goes down all its links are broken and no new links romp up. This is realized by its previous neighbors since all previous links to that node are reported to be broken. These nodes their report the disappearance of this node to other nodes by appending this information with their data packets or negation messages. When a new node comes up in the network, it listens to the transmissions of its neighbors to determine its connectivity and the slots available to it for communication. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the

The '496 Patent – Claims	Layer Net Reference
	number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. "Erroneous reception of data should also be reported to the node that sent the packet so that, the lost packet can be retransmitted." Layer Net at 846. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "If the distance from a node to any of its physical neighbors measured along the tree by the map is greater than two hops, a link is added connecting it to that neighbor. Using this rule any node can produce a new complete map of the entire network." Layer Net at 846-47.
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that	"A self-organizing multi-hop radio network is capable of creating its own topology and transmission schedules dynamically and in a distributed manner." Layer Net at 845.

The '496 Patent – Claims	Layer Net Reference
includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	"The self-organizing network is assumed to consist of nodes placed in such a way that all pairs of nodes are not directly connectable, but all nodes can be organized into a single multihop network." Layer Net at 845. "The network is comprised of links, where a link is defined as a permitted communication channel between nodes in range of each other. A 'starter node' is present that initiates the tree formation phase and coordinates other network organization procedures until the network starts functioning in a scheduled manner. Any node can serve as the starter node." Layer Net at 845. "During normal scheduled operation, a node tunes itself to listen to or transmit using a specific receiver directed code in each time slot in the schedule so that neighboring transmissions do not affect its operation. To prevent overlapping of transmissions, a suitable procedure should be followed for communication in each slot." Layer Net at 845. "In the initial 'network building' phase a starter node starts a broadcast that is rebroadcast by all nodes that hear it. As the broadcast propagates all the nodes learn the identity and location of all their neighbors. The connectivity information that is obtained during this broadcast is used by the starter node to organize a tree network. Links are then added to this initial tree to form a highly connected network." Layer Net at 846. "In the next 'scheduling' phase these links are scheduled in a distributed manner. Each node is assigned a layer number which is equal to its distance from the root measured in hops along the network. Schedules are made one layer at a time, starting from the starter node (layer 0). This nodes sets up a schedule for itself and transmits it to its one-hop neighbors (layer 1). These nodes then mark their own schedules and

The '496 Patent – Claims	Layer Net Reference
	interact to resolve conflicts, if any. Scheduling information is then sent to the layer 2 nodes and the process continues until all nodes have formed their respective schedules. At the end of this phase all links are scheduled to be activated once in the entire frame or slots. After this it forms links with some of its neighbors and schedules them in a conflict-free manner. This formation of links and the coming up of a new node are then reported to other nodes along with data packets or negation messages during scheduled operation. Note that once a scheduled network is formed, the number of additional nodes that can connect to it is limited by the number of available slots." Layer Net at 849. It would have been obvious to a person of ordinary skill in the art for the starter node to optimize the map transmitted down the tree in the manner claimed in order to provide an optimal starting point for the network. For example, such would eliminate the need for the downstream nodes to compute the optimal connectivity for initial network configuration, eliminating redundant processing.

Exhibit B9 – Invalidity Chart for Brownrigg Family based on Garcia-Luna-Aceves

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	"In a multihop PRNET, the nodes of the network are not all within one another's line of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434. "In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
	of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol	"In a multihop PRNET, the nodes of the network are not all within one another's line of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434. "In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
data packet with said header; and	
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
	NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
13. A method as recited in claim 10 further comprising maintaining a map	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435.

The '516 Patent – Claims	Garcia-Lunes-Aceves Reference
of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . .

	of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435.

The '314 Patent – Claims	Garcia-Lunes-Aceves Reference
	"Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
12. A first node providing a gateway	"In a multihop PRNET, the nodes of the network are not all within one another's line

Exhibit B9 – Invalidity Chart for Brownrigg Family based on Garcia-Luna-Aceves

The '314 Patent – Claims	Garcia-Lunes-Aceves Reference
between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network; a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434. "In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table

The '314 Patent – Claims	Garcia-Lunes-Aceves Reference
transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435.
wherein said digital controller changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and

	Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . .

The '471 Patent – Claims	Garcia-Lunes-Aceves Reference
	Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"If Node i changes one or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
12. A method as recited in claim 11, wherein said server process further	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '471 Patent – Claims	Garcia-Lunes-Aceves Reference
includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"In a multihop PRNET, the nodes of the network are not all within one another's line of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434. "In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '471 Patent – Claims	Garcia-Lunes-Aceves Reference
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every t_N seconds. After transmitting its last $NAND_i$, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing

The '471 Patent – Claims	Garcia-Lunes-Aceves Reference
	table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
send information identifying the server selected transmission path for each of the clients to the respective clients.	included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said	"If Node i changes one or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
comparison meets predetermined conditions.	
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435.

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
	"Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . . Using Procedure 1, each node sends a NAND to its neighbor every tN seconds. After transmitting its last NANDi, Node i . . . awaits the reception of NANDs from itself and its neighbors." maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and	"In a multihop PRNET, the nodes of the network are not all within one another's line of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434.

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
transmitting data packets via said second node radio modem,	"In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	"A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . .

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
	Using Procedure 1, each node sends a NAND to its neighbor every t_N seconds. After transmitting its last $NAND_i$, Node i . . . awaits the reception of NANDs from itself and its neighbors." Garcia-Luna-Aceves at 436. "Node i uses Procedure 1 to update its distance table upon the reception of any NAND." Garcia-Luna-Aceves at 436. "If Node i changes on or more entries in its distance table at the end of Procedure 1 and/or Procedure 2, it proceeds to update its routing table using Procedure 3." Garcia-Luna-Aceves at 437. "After computing the shortest distance to Node j, Node i makes certain that (1) the ancestor or next node to a destination is reachable, and (2) all the paths in the routing table contain only nodes known to be reachable." Garcia-Luna-Aceves at 437.
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data	"In a multihop PRNET, the nodes of the network are not all within one another's line of sight. Accordingly, packets may have to be forwarded through various nodes before they reach their destinations and each node must maintain a routing table to support packet forwarding." Garcia-Luna-Aceves at 434. "In a single-channel multihop PRNET a node can receive only one collision-free packet at a time from the radio channel." Garcia-Luna-Aceves at 434. "An update message is sent out periodically (but asynchronously) by each node." Garcia-Luna-Aceves at 435. It would have been obvious for a node in the network to serve as a gateway to, e.g.,

The '496 Patent – Claims	Garcia-Lunes-Aceves Reference
buffer in digital memory, and	the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Each node in the PRNET maintains three tables: a routing table, a distance table, and a good-neighbor table." Garcia-Luna-Aceves at 435. "Note that the information about immediate ancestors stored in the routing table defines a minimum-weight spanning tree, rooted at the node storing the routing table, that specifies the shortest path from the node to every other node in the network." Garcia-Luna-Aceves at 435. "A node determines the establishment of radio connectivity with a new neighbor when it receives a NAND from that neighbor." Garcia-Luna-Aceves at 435. "Because each node maintains a source tree in its routing table, routing of data packets can be accomplished in three ways: (1) incremental routing, (2) source routing, and (3) broadcast or multicast routing." Garcia-Luna-Aceves at 436. "In source routing, the source node specifies the NIDs of all the nodes in the path from source to destination based on the information stored in its source tree; that path is included in the header of the data packet." Garcia-Luna-Aceves at 436. "First, when a node is turned on, it initializes its routing and distance tables by means of Procedure 0. . . .

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The patent owner made a number of admissions during prosecution of the applications in, and proceedings regarding, the Brownrigg patent family.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Admitted Prior Art/Estoppel
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '516 Patent – Claims	Admitted Prior Art/Estoppel
the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2:	It would have been obvious for a node in the network to serve as a gateway to, e.g.,

The '516 Patent – Claims	Admitted Prior Art/Estoppel
wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the

The '516 Patent – Claims	Admitted Prior Art/Estoppel
said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '516 Patent – Claims	Admitted Prior Art/Estoppel
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '516 Patent – Claims	Admitted Prior Art/Estoppel
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Admitted Prior Art/Estoppel
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

The '314 Patent – Claims	Admitted Prior Art/Estoppel
of said plurality of second nodes; and	
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said second network; and a second data packet receiver	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '314 Patent – Claims	Admitted Prior Art/Estoppel
configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group consisting essentially of the path to first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
10. A client node in a network including a server node having a server radio modem and a server	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the

the fastest second nodes.	
13. A first node as recited in claim 12, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller converts data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
14. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver implementing a process to receive a data packet from a second node of said wireless network, a first converter implementing a process to convert said data packet to a format used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second network; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

The '314 Patent – Claims	Admitted Prior Art/Estoppel
a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Admitted Prior Art/Estoppel
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and

The '471 Patent – Claims	Admitted Prior Art/Estoppel
	maintenance of the network map, including the addition and deletion of nodes.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further comprises maintaining a client link tree having client link entries	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the

The '471 Patent – Claims	Admitted Prior Art/Estoppel
corresponding to an optimized transmission path for each of the plurality of clients, and	elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree)

The '471 Patent – Claims	Admitted Prior Art/Estoppel
selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
12. A method as recited in claim 11, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
of the remainder of said plurality of clients,	elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
path for each of the clients to the respective clients.	
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
	are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
second node link tree when said comparison meets predetermined conditions.	
19. A wireless network system as recited in claim 18 wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
the first node process further comprises maintaining a second node link tree having second node link entries.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
32. A wireless system as recited in claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
33. A wireless system as recited in claim 32, wherein the first node process further includes:	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley

The '471 Patent – Claims	Admitted Prior Art/Estoppel
logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	& Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
maintaining a second node link tree having second node link entries at the first node.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

The '471 Patent – Claims	Admitted Prior Art/Estoppel
said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	'062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree)

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '471 Patent – Claims	Admitted Prior Art/Estoppel
to the respective client node.	that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	Admitted Prior Art/Estoppel
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients;	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
and	
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic;	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling

The '496 Patent – Claims	Admitted Prior Art/Estoppel
server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the server selected transmission path, and send information identifying the server selected transmission path for each of the clients to the respective clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	Corp. and Kahn 78 references.
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree)

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
maintains a client link tree having client link entries representing each of the plurality of clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
12. A method for providing wireless network communication comprising: utilizing a server implementing a	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the

The '496 Patent – Claims	Admitted Prior Art/Estoppel
server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further includes maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process:	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	Corp. and Kahn 78 references.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree)

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein the server process: receives information identifying the	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the

The '496 Patent – Claims	Admitted Prior Art/Estoppel
selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	'062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
maintains a client link tree having client link entries representing each of the plurality of clients.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
17. A method for providing wireless network communication comprising the steps of: a server process including a data	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein the server process:	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element.

The '496 Patent – Claims	Admitted Prior Art/Estoppel
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
remainder of said plurality of second nodes,	
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.

The '496 Patent – Claims	Admitted Prior Art/Estoppel
conditions.	
23. A wireless network system as recited in claim 21, wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree)

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
buffer in a digital memory, and	that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
the second node configured to implement a second node process including: sending and receiving data packet via a second node wireless radio; maintaining a send/receive data buffer in a digital memory; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.
the first node comprising: a first node controller; and a first node radio modem, wherein said first node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting data packets via said first node radio modem; and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25.

The '496 Patent – Claims	Admitted Prior Art/Estoppel
second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010.

The '496 Patent – Claims	Admitted Prior Art/Estoppel

It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	The Brownrigg patents admit that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The Brownrigg patents admit that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. At a minimum, it would have been obvious to implement authentication of clients and

The '496 Patent – Claims	Admitted Prior Art/Estoppel
	maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Network Analysis Corp. and Kahn 78.
receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
determine a server selected	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element.

Exhibit B10 – Invalidity Chart for Brownrigg Family based on Admitted Prior Art/Estoppel

The '496 Patent – Claims	Admitted Prior Art/Estoppel
transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and	The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
maintain a client link tree having client link entries representing each of the plurality of client nodes.	Claims 1, 5, 9, and 13 of the '062 patent included, or rendered obvious, this element. The Board of Patent Appeals and Interferences affirmed the rejection of claim 1 of the '062 patent based on prior art on November 10, 2010. Brownrigg admitted that the elements of claim 1 and 9 were not patentably distinct from the prior art by cancelling claims 1, 5, 9, and 13 of the '062 patent on December 8, 2010. It would have been obvious for a gateway node to maintain a network map (or tree) that the node could optimize the network and determine efficient routes for communications with other nodes in the network, as discussed in the other references cited by Emerson, such as Dynamic Source Routing, Network Analysis Corp. and Kahn 78 references.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	It would have been obvious for the server node to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn

The Leiner reference, Leiner et al., "Issues in Packet Radio Network Design," 75 Proceedings of the IEEE, pp. 6-20 (Jan. 1987) (Leiner), includes descriptions relating to routing in packet radio networks.

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Leiner Reference
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological

The '516 Patent – Claims	Leiner Reference
second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
wherein said digital controller changes the transmission paths of	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be

The '516 Patent – Claims	Leiner Reference
clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their

The '516 Patent – Claims	Leiner Reference
	connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This

The '516 Patent – Claims	Leiner Reference
	can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '516 Patent – Claims	Leiner Reference
	"Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	"1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '516 Patent – Claims	Leiner Reference
	single network becomes partitioned." Leiner at 17.
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	"1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
5. A server as recited in claim 2:	"1) Gateways: Gateways can perform many functions but, as far as addressing is

The '516 Patent – Claims	Leiner Reference
wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and

Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual

The '516 Patent – Claims	Leiner Reference
	network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '516 Patent – Claims	Leiner Reference
	every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	"1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '516 Patent – Claims	Leiner Reference
	network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.

The '516 Patent – Claims	Leiner Reference
	"The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable

The '516 Patent – Claims	Leiner Reference
	approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. The '516 Patent – Claims	Leiner Reference

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Leiner Reference
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. 	arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the

The '314 Patent – Claims	Leiner Reference
	information." Leiner at 13-14.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity."
