a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

The '471 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

	alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting

The '471 Patent – Claims	Network Analysis References
	unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." NAC Dec. 1974, § 10.1.

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."

The '471 Patent – Claims	Network Analysis References
19. A wireless network system as recited in claim 18 wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175.

The '471 Patent – Claims	Network Analysis References
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '471 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

The '471 Patent – Claims	Network Analysis References
	implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8.

The '471 Patent – Claims	Network Analysis References
	"The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.

The '471 Patent – Claims	Network Analysis References
	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees

The '471 Patent – Claims	Network Analysis References
said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers,

	processing capabilities such as control, initialization, and accounting is called a station." Hahn at 42.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters

The '471 Patent – Claims	Network Analysis References
	sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
maintaining a second node link tree having second node link entries at the first node.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it

The '471 Patent – Claims	Network Analysis References
	does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '471 Patent – Claims	Network Analysis References
	path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
35. A method as recited in claim 34, wherein said first node process further includes:	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For

wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients; and	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL

The '496 Patent – Claims	Network Analysis References
	indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a

The '496 Patent – Claims	Network Analysis References
plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and	hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it

The '496 Patent – Claims	Network Analysis References
	determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater.

The '496 Patent – Claims	Network Analysis References
	Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6.

	answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus

The '496 Patent – Claims	Network Analysis References
	reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.

The '496 Patent – Claims	Network Analysis References
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned

	answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25.

The '496 Patent – Claims	Network Analysis References
determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to

The '496 Patent – Claims	Network Analysis References
	avoid use of the illegitimate client.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps:

The '496 Patent – Claims	Network Analysis References
	STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical

It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.

The '496 Patent – Claims	Network Analysis References
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned

The '496 Patent – Claims	Network Analysis References
	answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25.

The '496 Patent – Claims	Network Analysis References
determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '496 Patent – Claims	Network Analysis References
	avoid use of the illegitimate client.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps:

The '496 Patent – Claims	Network Analysis References
	STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical

The '496 Patent – Claims	Network Analysis References
	algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater.

The '496 Patent – Claims	Network Analysis References
	… Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an

The '496 Patent – Claims	Network Analysis References
	indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein said server process further includes maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process:	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a

The '496 Patent – Claims	Network Analysis References
	hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it

The '496 Patent – Claims	Network Analysis References
	determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in

The '496 Patent – Claims	Network Analysis References
	network topology occur." Hahn at 43.
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." 	algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '496 Patent – Claims	Network Analysis References
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175.

The '496 Patent – Claims	Network Analysis References
	To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

The '496 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

The '496 Patent – Claims	Network Analysis References
	implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8.

The '496 Patent – Claims	Network Analysis References
	"The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an

The '496 Patent – Claims	Network Analysis References
	acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can

The '496 Patent – Claims	Network Analysis References
	accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
maintains a client link tree having client link entries representing each of the plurality of clients. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175.

The '496 Patent – Claims	Network Analysis References
	To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above

The '496 Patent – Claims	Network Analysis References
	repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at

The '496 Patent – Claims	Network Analysis References
	927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment, it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the

The '496 Patent – Claims	Network Analysis References
	failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928.

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '496 Patent – Claims	Network Analysis References
	"This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." NAC Dec. 1974, § 10.1.

	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

The '496 Patent – Claims	Network Analysis References
	implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8.

The '496 Patent – Claims	Network Analysis References
	"The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. 	exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical

The '496 Patent – Claims	Network Analysis References
	algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."

selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

The '496 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." NAC Dec. 1974, § 10.1.

maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I

The '496 Patent – Claims	Network Analysis References
	Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central

The '496 Patent – Claims	Network Analysis References
	site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes.

The '496 Patent – Claims	Network Analysis References
dynamically updating said second node link tree when said comparison meets predetermined conditions.	Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For

The '496 Patent – Claims	Network Analysis References
	example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '496 Patent – Claims	Network Analysis References
inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during initialization. Repeaters determine primary label, secondary label, etc., according to distance, in number of hops, to the corresponding stations. Order may be changed upon changes in network topology." Gitman at 928. "Transmission power is increased when blocking is encountered, instead of the ALL indicator. All repeaters on the preferred path that are closer to the destination can accept the packet. The advantage of this technique is that one can shorten the number of hops to the destination and bypass failed repeaters." Gitman at 928. "This generalization involves the search for an alternate repeater when encountering blocking. A 'search' protocol uses a search packet specifying the class of repeaters sought. A response by such a repeater contains the hierarchical label of the responding repeater. The searching repeater substitutes the label of the responding

The '496 Patent – Claims	Network Analysis References
	repeater into the original packet and transmits the packet." Gitman at 929. "If a repeater along the required path has failed, all is not lost. When a repeater exceeds its allowed number of retransmissions without receiving an acknowledgment., it can set a bit in the header instructing all repeaters to adopt the flooding algorithm for the packet. This begins an alternate routing procedure and a failed or temporarily busy repeater may be bypassed. It could also announce the failure to the central site, requesting the central site to conduct another probe and relabel the tree. Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I

Exhibit B3 – Invalidity Chart for Brownrigg Family based on Network Analysis Corporation References

The '496 Patent – Claims	Network Analysis References
	Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central

The '496 Patent – Claims	Network Analysis References
	site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928.

The '496 Patent – Claims	Network Analysis References
	"Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations

The '496 Patent – Claims	Network Analysis References
	already in its cache."
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4. Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175.

The '496 Patent – Claims	Network Analysis References
	To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under

The '496 Patent – Claims	Network Analysis References
	implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8.

The '496 Patent – Claims	Network Analysis References
	"The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would

The '496 Patent – Claims	Network Analysis References
said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	allow the station to react to network changes and faster updates of labels. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.

The '496 Patent – Claims	Network Analysis References
	To the extent not disclosed or inherent in the Network Analysis Corp. references, it would have been obvious to a person of ordinary skill in the art to compare the label used by the packet headers of the repeaters to the label expected by the station. For example, when a path is blocked, the repeaters search for a new label or use an alternate label. Allowing the station to compare the label and update the tree would allow the station to react to network changes and faster updates of labels. Such use of a route cache is suggested by David B. Johnson, "Routing in Ad Hoc Networks of Mobile Hosts," Proceedings of the IEEE Workshop on Mobile Computing Systems and Applications (Dec. 1994) ("Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examin[in]g the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache."
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree	The '062 patent admits that "[a]uthentication techniques are well known to those skilled in the art. For example, the book, incorporated herein by reference, Algorithms in SNOBOL 4, by James F. Gimpel, Bell Telephone Laboratories, John Wiley & Sons, a Wiley Interscience Publication, © 1976 by Bell Telephone Labs, Inc., ISBN 0-471-30213-9, describes authentication techniques using one-way seeds." '062 patent at 15:18-25. The '062 patent also admits that "[t]he addition and removal of nodes from trees are well known to those skilled in the art. For example, in the book, incorporated herein by reference, SNOBOL 4: Techniques and Applications, by Ralph E. Griswald, Department of Computer Science, University of Arizona, Prentiss-Hall, Inc., .COPYRGT. 1975, ISBN 0-13-853010-6, algorithms for placing and removing clients from trees are discussed." '062 patent at 14:65-15:4.

The '496 Patent – Claims	Network Analysis References
if said second node is authentic and is not already in said client link tree.	Flanders is directed towards protecting subscribers in wireless telecommunications systems. Specifically, Flanders teaches authenticating clients before enabling communications with said clients. In addition, Flanders teaches restricting unauthenticated users from participating in wireless communications within a wireless communications network. See, e.g., Flanders at 4:8-12, 4:32-36. column 14:51-52; 15:18-19. Wey is directed towards authentication m mobile communications systems. Specifically, Wey discloses authenticating the identity of a subscribing unit (i.e., client), enabling communications if the identity is authenticated, and denying communications if the identity is unauthenticated. See, e.g., Wey at 175. To the extent not disclosed or inherent in the Network Analysis Corp., such features would have been obvious to a person of ordinary skill in the art. A person of ordinary skill in the art would have found it obvious to authenticate clients wishing to join a network. Authentication would have several benefits, including reduction in traffic, separation of data, preclusion of eavesdropping, etc. In such a system having authentication, legitimate clients would be obviously added to the client link tree (or removed from the tree based on, e.g., operational status). Illegitimate clients would be excluded from the network and, obviously, removed from the client link tree so as to avoid use of the illegitimate client.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data	"There are three basic functional components of the Packet Radio System: the Packet Radio Terminal, the Packet Radio Station, and the Packet Radio Repeater. (See Figure 10.1.) Packet Radio Terminals will be of various types, including personal digital terminals, TTY-like devices, unattended sensors, small computers, display printers, and position location devices." Another alternate routing method when blocking is encountered is simply to turn up its transmission power and hope to skip over the failed repeater." Hahn at 44.
maintain a client link tree having client link entries representing each of the plurality of client nodes.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity

The '496 Patent – Claims	Network Analysis References
	matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927.

The '496 Patent – Claims	Network Analysis References
	"The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"In some applications the Packet Radio Station will be the interface component between the broadcast system and a point-to-point network. As such it will have broadcast channels into the Packet Radio System and Link channels into the point-to-point network. In addition, it will perform accounting, buffering, directory, and routing functions for the overall system." NAC Dec. 1974, § 10.1. "Stations Among the stations' functional capabilities are: a. A directory of terminals and repeaters in its region.

The '496 Patent – Claims	Network Analysis References
	b. Operations necessary to convert packets from the Packet Radio System into packets used in the point-to-point network and conversely. c. Storage buffers for packets received from terminals and for packets to be transmitted to terminals. d. Storage for character position information for active terminals which do not have this capability. e. Accounting capabilities. f. Capabilities related to routing, flow control, and network management." NAC Dec. 1974, § 10.2.1. *See also* NAC Dec. 1973 at §§ 9-10. *See also* NAC Jun. 1974 at pp. 7.1-7.52 (discussing packet handling in the packet radio network having hierarchical routing); 7.69-70 (discussing labeling and discovery of creation of network topology ("connectivity matrix")). "The network model we examine contains a large number of nodes using random transmission schemes and omnidirectional antennas. The network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional capabilities such as gateway, global control, global initialization, accounting, and directory functions, is called a station." Gitman at 927. "Typically, a radio network contains two types of nodes. A node with origination, destination, and relay functions is called a repeater. A node with additional processing capabilities such as control, initialization, and accounting is called a station." Hahn at 42.

The '496 Patent – Claims	Network Analysis References
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	"The station will determine and assign labels to all repeaters in its area in the initial labeling procedure. When more than one station operates in an area, the initial labeling will be done by the stations sequentially, and repeaters may be allowed to choose the home station according to the minimum number of hops." NAC Dec. 1973 at pp. 10.27-10.33. "The information acquired from the response packets is sufficient to determine a hierarchical labeling structure. In this step, the station processes the information and determines an "optimized" structure. The processing performed during this step is described in the next section." NAC Dec. 1973 at pp. 10.27-10.33. "The approach that we adopted is to use the flooding routing algorithm to load repeaters with hierarchical labels. The flooding algorithm was selected because it does not require any knowledge of the topology of the network. A process for repeater initialization and labelling which has been detailed in [6] is currently under implementation. Initially, it is assumed that the station contains a set of fixed identifiers of repeaters which may possibly be connected into a network; three stages are then followed. In stage 1 the station transmits special control packets to the above repeaters, and repeaters respond with control packets from which a connectivity matrix between repeaters is established. The hierarchical labels are determined in stage 2 from the connectivity matrix. In stage 3 the station transmits the labels to repeaters and tests each path in both directions, from station to repeater and from repeater to station." NAC Jun. 1974 at pp. 7.69-70. "The process contains three steps: STEP I

The '496 Patent – Claims	Network Analysis References
	Mapping the network connectivity. This is obtained by a process in which stations transmit packets to repeaters, requesting each to respond with a trace packet into which every repeater along the path adds its fixed ID. STEP II Determining network structure. The connectivity information obtained above is used to obtain a network structure which has several properties; for example, it enables every packet to be routed along the shortest path (minimum number of hops); it determines the repeaters which are not needed for relaying packets and which should be temporarily disabled … STEP III In this step, the stations transmit the structure information to repeaters and test each path in both directions." NAC Dec. 1974 at pp. 11.6-11.8. "The broadcast routing algorithm floods either the network or a subset of nodes. Flooding can be utilized by stations to map network connectivity so that routing information can be assigned to repeaters to obtain more efficient routing." Gitman at 927. "The routing strategy identifies shortest path (minimum hop) between repeaters and stations, and prevents, wherever possible, generation of duplicate copies of packets. The routing is sufficiently flexible to allow departures from the first choice path and use of next shortest paths." Gitman at 928. "Furthermore, the fact that all packets are routed via a station, in the hierarchical algorithm, enables easy monitoring of network connectivity and faster updating of

The '496 Patent – Claims	Network Analysis References
	labels." Gitman at 930. "In single-station hierarchical routing, it is required that the central site be aware of the complete network topology. This information is acquired by having the central site send broadcast probe packets periodically. Each repeater responds to a probe by sending an answer packet. When a repeater forwards an answer packet due to another repeater, it appends its identification to the packet. From the returned answers. the central site can easily determine the shortest path to each repeater. Upon learning the new topology, the central site assigns routing information to repeaters. This information assigned by a station is called a label. The set of repeater labels forms a hierarchical tree structure of repeaters rooted at the station, as shown in Fig. 2. The labels may be changed during network operation when changes in network topology occur." Hahn at 43. "Suppose that L_{ij} along the shortest path is not successful in transmitting the packet to $h(L_{ij})$. Then L_{ij} begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1973. "Suppose that Lij along the shortest path is not successful in transmitting the packet to h(Lij). Then Lij begins the search stage of trying to identify another repeater. … Note that if repeaters have sufficient storage, they can save alternative labels and thus reduce the necessity of searching for a specific repeater. " NAC Dec. 1974 at pp. 13.6. "In a multistation network, repeaters are assigned labels by several stations during

packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
	100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows.

The '516 Patent – Claims	Meier References
	Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length)

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
	RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the

The '516 Patent – Claims	Meier References
	root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal

The '516 Patent – Claims	Meier References
consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	that is not contained in the routing table of the node, an entry is made in the routing table. When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then

The '516 Patent – Claims	Meier References
	all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.

The '516 Patent – Claims	Meier References
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	"Gateways are used to pass messages to and from a host computer and the RF Network. A host port is used to provide a link between the gateway and the host computer." Meier '436 at 2:26-28. "In one embodiment of the present invention, the RF data communication system has a host computer 10, a network controller 14 and bridges 22 and 24 attached to a data communication link 16. Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention." Meier '436 at 3:5-11. "The responsibilities of the transport layer include the following. 1) Establishing and maintaining TCP-like connections for reliable root-to-terminal data transmission." Meier '436 at 11:20-23. "The transport layer provides reliable, unreliable, and transaction-oriented services. Two types of transport connections are defined: l) a TCP-like transport connection may be explicitly requested for long-lived connections or 2) a VMTP-like connection-record may be implicitly set up for transient connections. In addition, a connectionless service is provided for nodes which support an end-to-end transport connection with the host computer." Meier '436 at 16:54-62. It would have been obvious for a person of ordinary skill to use the TCP/IP protocol to transfer messages along data link 16 in Meier '436, e.g., translating messages from a host computer to another computer and vice versa, in order to provide a protocol for sending and receiving packets in a connection-oriented manner. TCP/IP was known to be a reliable, and well-used, protocol for such communications.

4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	"Gateways are used to pass messages to and from a host computer and the RF Network. A host port is used to provide a link between the gateway and the host computer." Meier '436 at 2:26-28. "In one embodiment of the present invention, the RF data communication system has a host computer 10, a network controller 14 and bridges 22 and 24 attached to a data communication link 16. Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention." Meier '436 at 3:5-11. "The responsibilities of the transport layer include the following. 2) Establishing and maintaining TCP-like connections for reliable root-to-terminal data transmission." Meier '436 at 11:20-23. "The transport layer provides reliable, unreliable, and transaction-oriented services. Two types of transport connections are defined: l) a TCP-like transport connection may be explicitly requested for long-lived connections or 2) a VMTP-like connection-record may be implicitly set up for transient connections. In addition, a connectionless service is provided for nodes which support an end-to-end transport connection with the host computer." Meier '436 at 16:54-62. It would have been obvious for a person of ordinary skill to use the TCP/IP protocol to transfer messages along data link 16 in Meier '436, e.g., translating messages from a host computer to another computer and vice versa, in order to provide a protocol for sending and receiving packets in a connection-oriented manner. TCP/IP was known to be a reliable, and well-used, protocol for such communications.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	"Gateways are used to pass messages to and from a host computer and the RF Network. A host port is used to provide a link between the gateway and the host computer." Meier '436 at 2:26-28. "In one embodiment of the present invention, the RF data communication system has a host computer 10, a network controller 14 and bridges 22 and 24 attached to a data communication link 16. Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention." Meier '436 at 3:5-11. "The responsibilities of the transport layer include the following. 3) Establishing and maintaining TCP-like connections for reliable root-to-terminal data transmission." Meier '436 at 11:20-23. "The transport layer provides reliable, unreliable, and transaction-oriented services. Two types of transport connections are defined: l) a TCP-like transport connection may be explicitly requested for long-lived connections or 2) a VMTP-like connection-record may be implicitly set up for transient connections. In addition, a connectionless service is provided for nodes which support an end-to-end transport connection with the host computer." Meier '436 at 16:54-62. It would have been obvious for a person of ordinary skill to use the TCP/IP protocol to transfer messages along data link 16 in Meier '436, e.g., translating messages from a host computer to another computer and vice versa, in order to provide a protocol for sending and receiving packets in a connection-oriented manner. TCP/IP was known to be a reliable, and well-used, protocol for such communications.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
	It also would have been obvious to include a packet type and source route path to packets received by the gateway in order to provide a defined route to a terminal. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '516 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals

The '516 Patent – Claims	Meier References
	100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows.

The '516 Patent – Claims	Meier References
	Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

The '516 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length)

The '516 Patent – Claims	Meier References
	RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. "As a result of the backward learning, once the root node receives the ATTACH.request packet, an ATTACH.response packet can be sent through the spanning tree to the bridge requesting attachment." Meier '436 at 5:36-39. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table

	bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Meier References
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '314 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '314 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '314 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '314 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '314 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '314 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '314 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '314 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '314 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '314 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. 	"Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset

The '314 Patent – Claims	Meier References
	priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-

The '314 Patent – Claims	Meier References
	10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is

The '314 Patent – Claims	Meier References
	overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-

The '314 Patent – Claims	Meier References
	like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group consisting essentially of the path to first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a

The '314 Patent – Claims	Meier References
	base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the

	bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising: a client node radio modem; and a client node controller; said client node controller implementing a process	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
including receiving and transmitting data packets via said client modem;	"The present invention comprises an RF Local Area Network..." Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1: FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the

The '314 Patent – Claims	Meier References
	root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node

The '314 Patent – Claims	Meier References
	consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the

The '314 Patent – Claims	Meier References
	network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value.

The '314 Patent – Claims	Meier References
	If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
selecting a radio transmission path to said server node that is one of a direct link to said server node and an indirect link to said server node through at least one other client node;	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO

The '314 Patent – Claims	Meier References
	packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44

The '314 Patent – Claims	Meier References
	send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the

The '314 Patent – Claims	Meier References
	bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the

The '314 Patent – Claims	Meier References
	bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately

The '314 Patent – Claims	Meier References
	according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message,

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by

optimized transmission path.	monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and

The '314 Patent – Claims	Meier References
	the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be

	reversed." Meier '436 at 4:54-5:19.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network; a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

The '314 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '314 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '314 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '314 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

	reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and

The '314 Patent – Claims	Meier References
the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in

The '314 Patent – Claims	Meier References
	DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Meier References
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '471 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '471 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of

The '471 Patent – Claims	Meier References
	polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge

The '471 Patent – Claims	Meier References
	attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node

The '471 Patent – Claims	Meier References
	20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11.

The '471 Patent – Claims	Meier References
	"Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17.

The '471 Patent – Claims	**Meier References**
	"Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	computer." Meier '436 at 2:26-28. "In one embodiment of the present invention, the RF data communication system has a host computer 10, a network controller 14 and bridges 22 and 24 attached to a data communication link 16. Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention." Meier '436 at 3:5-11. "The responsibilities of the transport layer include the following. 6) Establishing and maintaining TCP-like connections for reliable root-to-terminal data transmission." Meier '436 at 11:20-23. "The transport layer provides reliable, unreliable, and transaction-oriented services. Two types of transport connections are defined: l) a TCP-like transport connection may be explicitly requested for long-lived connections or 2) a VMTP-like connection-record may be implicitly set up for transient connections. In addition, a connectionless service is provided for nodes which support an end-to-end transport connection with the host computer." Meier '436 at 16:54-62. It would have been obvious for a person of ordinary skill to use the TCP/IP protocol to transfer messages along data link 16 in Meier '436, e.g., translating messages from a host computer to another computer and vice versa, in order to provide a protocol for sending and receiving packets in a connection-oriented manner. TCP/IP was known to be a reliable, and well-used, protocol for such communications.
4. A wireless network system as recited in claim 3, wherein said server	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	"FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF

The '471 Patent – Claims	Meier References
	links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the

The '471 Patent – Claims	Meier References
	software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

The '471 Patent – Claims	Meier References
	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said server that is one of a direct link to	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the

The '471 Patent – Claims	Meier References
said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

The '471 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO

The '471 Patent – Claims	Meier References
	packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by

The '471 Patent – Claims	Meier References
	monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the

The '471 Patent – Claims	Meier References
	data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment

The '471 Patent – Claims	Meier References
	to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the

The '471 Patent – Claims	Meier References
	packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must

The '471 Patent – Claims	Meier References
	remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge

The '471 Patent – Claims	Meier References
	forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37.

The '471 Patent – Claims	Meier References
	"After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data

The '471 Patent – Claims	Meier References
	packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the

The '471 Patent – Claims	Meier References
	contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.)

The '471 Patent – Claims	Meier References
	2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree.

The '471 Patent – Claims	Meier References
	For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically,

The '471 Patent – Claims	Meier References
	SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system."

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	"Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all

The '471 Patent – Claims	Meier References
	non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver

The '471 Patent – Claims	Meier References
	SST or UHF (701)").
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When

The '471 Patent – Claims	Meier References
	the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each

The '471 Patent – Claims	Meier References
	node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path.

The '471 Patent – Claims	Meier References
	4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly.

The '471 Patent – Claims	Meier References
transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop

The '471 Patent – Claims	Meier References
	in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note

The '471 Patent – Claims	Meier References
	that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the

The '471 Patent – Claims	Meier References
	ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only

The '471 Patent – Claims	Meier References
	nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44.

The '471 Patent – Claims	Meier References
	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	"Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops

The '471 Patent – Claims	Meier References
	needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the

The '471 Patent – Claims	Meier References
	message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old

The '471 Patent – Claims	Meier References
	path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
12. A method as recited in claim 11, wherein said server process further	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer

The '471 Patent – Claims	Meier References
	10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43.

The '471 Patent – Claims	Meier References
	"A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for

The '471 Patent – Claims	Meier References
	terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be

	reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
clients,	gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge

The '471 Patent – Claims	Meier References
	determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For

The '471 Patent – Claims	Meier References
	example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing

The '471 Patent – Claims	Meier References
	table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data

The '471 Patent – Claims	Meier References
	packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid

The '471 Patent – Claims	Meier References
	instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child

The '471 Patent – Claims	Meier References
	base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists.

The '471 Patent – Claims	Meier References
	5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how

The '471 Patent – Claims	Meier References
	to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After

The '471 Patent – Claims	Meier References
	receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer

The '471 Patent – Claims	Meier References
	directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge

The '471 Patent – Claims	Meier References
	attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a

The '471 Patent – Claims	Meier References
	child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new

The '471 Patent – Claims	Meier References
	path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.

The '471 Patent – Claims	Meier References
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1: FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A

The '471 Patent – Claims	Meier References
	bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-

The '471 Patent – Claims	Meier References
	oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").

The '471 Patent – Claims	Meier References
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and

The '471 Patent – Claims	Meier References
	ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the

The '471 Patent – Claims	Meier References
	ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and

The '471 Patent – Claims	Meier References
	all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its

The '471 Patent – Claims	Meier References
	routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the

The '471 Patent – Claims	Meier References
	logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. The '471 Patent – Claims	Meier References
	all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.

The '471 Patent – Claims	Meier References
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets

The '471 Patent – Claims	Meier References
	and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44

The '471 Patent – Claims	Meier References
	request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node

The '471 Patent – Claims	Meier References
	returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When

The '471 Patent – Claims	Meier References
	the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO

The '471 Patent – Claims	Meier References
	message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each

The '471 Patent – Claims	Meier References
	node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path.

The '471 Patent – Claims	Meier References
	4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
19. A wireless network system as recited in claim 18 wherein said first node process further comprises: logic determining if one of the	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks."

The '471 Patent – Claims	Meier References
plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-

The '471 Patent – Claims	Meier References
memory, and	18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link

The '471 Patent – Claims	Meier References
	and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service

The '471 Patent – Claims	Meier References
	detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is

The '471 Patent – Claims	Meier References
	sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a link to said first node that	"To initialize the RF data communication system, the gateway 20 and the other nodes

However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal.

The '471 Patent – Claims	Meier References
	If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is

The '471 Patent – Claims	Meier References
	overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the

The '471 Patent – Claims	Meier References
	node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED

The '471 Patent – Claims	Meier References
	LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing

The '471 Patent – Claims	Meier References
	table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a

The '471 Patent – Claims	Meier References
	DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state.

The '471 Patent – Claims	Meier References
	Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the

The '471 Patent – Claims	Meier References
	gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the

The '471 Patent – Claims	Meier References
	ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with

The '471 Patent – Claims	Meier References
	another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the

The '471 Patent – Claims	Meier References
	attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	"Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a

The '471 Patent – Claims	Meier References
	bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000."

The '471 Patent – Claims	Meier References
	Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state.

The '471 Patent – Claims	Meier References
	Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the

The '471 Patent – Claims	Meier References
	gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with

The '471 Patent – Claims	Meier References
	another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning

The '471 Patent – Claims	Meier References
	tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path.

The '471 Patent – Claims	Meier References
	4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
the first node process further comprises maintaining a second node link tree having second node link entries.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and

The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing

The '471 Patent – Claims	Meier References
	tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F.	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1: 
The '471 Patent – Claims	Meier References
	"Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset

The '471 Patent – Claims	Meier References
	priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-

The '471 Patent – Claims	Meier References
	10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is

The '471 Patent – Claims	Meier References
	overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-

The '471 Patent – Claims	Meier References
	like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to

The '471 Patent – Claims	Meier References
	the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is

The '471 Patent – Claims	Meier References
	discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an

The '471 Patent – Claims	Meier References
	appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the

The '471 Patent – Claims	Meier References
	data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '471 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one

The '471 Patent – Claims	Meier References
	exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing

The '471 Patent – Claims	Meier References
	tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.

The '471 Patent – Claims	Meier References
maintaining a second node link tree having second node link entries at the first node.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. The '471 Patent – Claims	Meier References
	attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37.

The '471 Patent – Claims	Meier References
	"After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent

The '471 Patent – Claims	Meier References
	node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge

The '471 Patent – Claims	Meier References
	determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node

The '471 Patent – Claims	Meier References
	is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree.

The '471 Patent – Claims	Meier References
	For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is

The '471 Patent – Claims	Meier References
	CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem;	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the

The '471 Patent – Claims	Meier References
and a server node controller implementing a server process, said server process configured to: receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at

The '471 Patent – Claims	Meier References
	2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal

The '471 Patent – Claims	Meier References
	nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '471 Patent – Claims	Meier References
	A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid

The '471 Patent – Claims	Meier References
	instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a

The '471 Patent – Claims	Meier References
	particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes to the respective client node.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the

	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients; and	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11.

The '496 Patent – Claims	Meier References
client link entries representing each of the plurality of clients.	"The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1: 
The '496 Patent – Claims	Meier References
	"Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single

The '496 Patent – Claims	Meier References
	root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The

The '496 Patent – Claims	Meier References
	MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle)

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet.

The '496 Patent – Claims	Meier References
	The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and

The '496 Patent – Claims	Meier References
	221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically

The '496 Patent – Claims	Meier References
	broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its

The '496 Patent – Claims	Meier References
	attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.)

The '496 Patent – Claims	Meier References
	2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the

The '496 Patent – Claims	Meier References
	spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any

The '496 Patent – Claims	Meier References
	changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast.

The '496 Patent – Claims	Meier References
	By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets

The '496 Patent – Claims	Meier References
	(at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root

The '496 Patent – Claims	Meier References
	node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal."

The '496 Patent – Claims	Meier References
	Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

The '496 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network

The '496 Patent – Claims	Meier References
	entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root,

The '496 Patent – Claims	Meier References
	must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO

The '496 Patent – Claims	Meier References
	packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66.

The '496 Patent – Claims	Meier References
	"Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same

The '496 Patent – Claims	Meier References
	branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39.

The '496 Patent – Claims	Meier References
	"When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier

The '496 Patent – Claims	Meier References
	'436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.

The '496 Patent – Claims	Meier References
	"DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. The '496 Patent – Claims	Meier References
	FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19.

The '496 Patent – Claims	Meier References
	"In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station

The '496 Patent – Claims	Meier References
	contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of

The '496 Patent – Claims	Meier References
	polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge

The '496 Patent – Claims	Meier References
	attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node

The '496 Patent – Claims	Meier References
	20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17.

The '496 Patent – Claims	Meier References
	"Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value.

The '496 Patent – Claims	**Meier References**
	If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal.

The '496 Patent – Claims	Meier References
	IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

The '496 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10.

The '496 Patent – Claims	Meier References
	"Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table

The '496 Patent – Claims	Meier References
	for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

The '496 Patent – Claims	Meier References
	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES

The '496 Patent – Claims	Meier References
	CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED

The '496 Patent – Claims	Meier References
	LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the

The '496 Patent – Claims	Meier References
correspond to the server selected transmission path between the server and the respective client.	optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO

The '496 Patent – Claims	Meier References
	packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by

The '496 Patent – Claims	Meier References
	monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the

The '496 Patent – Claims	Meier References
	data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station,

The '496 Patent – Claims	Meier References
housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are

The '496 Patent – Claims	Meier References
	sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc.

The '496 Patent – Claims	Meier References
	2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3.

The '496 Patent – Claims	Meier References
	"Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35.

The '496 Patent – Claims	Meier References
	"The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36.

The '496 Patent – Claims	Meier References
	"Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44.

The '496 Patent – Claims	Meier References
	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65.

The '496 Patent – Claims	Meier References
	"Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

The '496 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to

The '496 Patent – Claims	Meier References
	deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-

The '496 Patent – Claims	Meier References
	end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein the server process: receives information identifying the	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the

Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
maintains a client link tree having client link entries representing each of the plurality of clients.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent

The '496 Patent – Claims	Meier References
	the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.

The '496 Patent – Claims	Meier References
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further includes maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process:	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent

The '496 Patent – Claims	Meier References
	the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment

The '496 Patent – Claims	Meier References
	if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next

The '496 Patent – Claims	Meier References
	hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists.

The '496 Patent – Claims	Meier References
	5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which

The '496 Patent – Claims	Meier References
	flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request

The '496 Patent – Claims	Meier References
	packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer.

The '496 Patent – Claims	Meier References
	However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base

The '496 Patent – Claims	Meier References
	station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a

The '496 Patent – Claims	Meier References
between the server and the respective client.	status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes

The '496 Patent – Claims	Meier References
	attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal

The '496 Patent – Claims	Meier References
	that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals

The '496 Patent – Claims	Meier References
	is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks

The '496 Patent – Claims	Meier References
	having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the

The '496 Patent – Claims	Meier References
	terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists.

The '496 Patent – Claims	Meier References
	During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the

The '496 Patent – Claims	Meier References
client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at

The '496 Patent – Claims	Meier References
	2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal

The '496 Patent – Claims	Meier References
	nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer

The '496 Patent – Claims	Meier References
	A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid

The '496 Patent – Claims	Meier References
	instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a

The '496 Patent – Claims	Meier References
	particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only

The '496 Patent – Claims	Meier References
	nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44.

The '496 Patent – Claims	Meier References
	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65.

The '496 Patent – Claims	Meier References
	"Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops

The '496 Patent – Claims	Meier References
	needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the

"The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes

The '496 Patent – Claims	Meier References
	attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal

The '496 Patent – Claims	Meier References
	that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals

The '496 Patent – Claims	Meier References
	is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks

The '496 Patent – Claims	Meier References
	having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the

The '496 Patent – Claims	Meier References
	terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists.

The '496 Patent – Claims	Meier References
	During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
maintains a client link tree having client link entries representing each of the plurality of clients.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11.

The '496 Patent – Claims	Meier References
	"Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.

The '496 Patent – Claims	**Meier References**
17. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

The '496 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. The '496 Patent – Claims	Meier References
	in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35.

The '496 Patent – Claims	Meier References
	"The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically

The '496 Patent – Claims	Meier References
	closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal."

The '496 Patent – Claims	Meier References
	Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node.

The '496 Patent – Claims	Meier References
	The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network

The '496 Patent – Claims	Meier References
	entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root,

The '496 Patent – Claims	Meier References
	must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.

The '496 Patent – Claims	Meier References
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal

The '496 Patent – Claims	Meier References
	address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
21. A wireless network system comprising: a first node including a first node	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal

The '496 Patent – Claims	Meier References
controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11.

The '496 Patent – Claims	Meier References
	"The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its

The '496 Patent – Claims	Meier References
	attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20

The '496 Patent – Claims	Meier References
	and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11.

The '496 Patent – Claims	Meier References
	"Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17.

The '496 Patent – Claims	Meier References
	"Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value.

The '496 Patent – Claims	Meier References
	If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal.

The '496 Patent – Claims	Meier References
	IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state

The '496 Patent – Claims	Meier References
	whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
23. A wireless network system as recited in claim 21, wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. The '496 Patent – Claims	Meier References
	"FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF

The '496 Patent – Claims	Meier References
	links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the

The '496 Patent – Claims	Meier References
	software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable

The '496 Patent – Claims	Meier References
	services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
maintaining a second node link tree having second node link entries	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node

The '496 Patent – Claims	Meier References
representing each of the plurality of second nodes; dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the

The '496 Patent – Claims	Meier References
	following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet.

The '496 Patent – Claims	Meier References
	The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and

The '496 Patent – Claims	Meier References
	221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically

The '496 Patent – Claims	Meier References
	broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its

The '496 Patent – Claims	Meier References
	attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.)

The '496 Patent – Claims	Meier References
	2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the

The '496 Patent – Claims	Meier References
	spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any

The '496 Patent – Claims	Meier References
	changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

The '496 Patent – Claims	Meier References
	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include:

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." 	detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is

The '496 Patent – Claims	Meier References
	sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
initiating a radio transmission path to	"To initialize the RF data communication system, the gateway 20 and the other nodes

The '496 Patent – Claims	Meier References
a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication

The '496 Patent – Claims	Meier References
	network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached

The '496 Patent – Claims	Meier References
	bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly.

The '496 Patent – Claims	Meier References
	This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal.

The '496 Patent – Claims	Meier References
	If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is

The '496 Patent – Claims	Meier References
	overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED

The '496 Patent – Claims	Meier References
	LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
the first node comprising: a first node controller; and a first node radio modem, wherein said first node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station,

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
data packets via said first node radio modem; and	the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are

The '496 Patent – Claims	Meier References
	sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc.

The '496 Patent – Claims	Meier References
	2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks

The '496 Patent – Claims	Meier References
	having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5.

	attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up

The '496 Patent – Claims	Meier References
	the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from

The '496 Patent – Claims	Meier References
	other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an

The '496 Patent – Claims	Meier References
	upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be

The '496 Patent – Claims	Meier References
	reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED.

The '496 Patent – Claims	Meier References
	When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the

The '496 Patent – Claims	Meier References
	detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks." Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
36. In a wireless network system comprising a plurality of second	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one

The '496 Patent – Claims	Meier References
nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:

	FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network

The '496 Patent – Claims	Meier References
	controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a

The '496 Patent – Claims	Meier References
	network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44.

initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68.

The '496 Patent – Claims	Meier References
	"HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically

The '496 Patent – Claims	Meier References
	closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using

The '496 Patent – Claims	Meier References
	the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals

The '496 Patent – Claims	Meier References
	(i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to

The '496 Patent – Claims	Meier References
	the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT

The '496 Patent – Claims	Meier References
	PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link

The '496 Patent – Claims	Meier References
	and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function.

The '496 Patent – Claims	Meier References
	3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service

The '496 Patent – Claims	Meier References
	detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
selecting a transmission path to said	"To initialize the RF data communication system, the gateway 20 and the other nodes

The '496 Patent – Claims	Meier References
first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication

The '496 Patent – Claims	Meier References
	network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached

The '496 Patent – Claims	Meier References
	bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly.

The '496 Patent – Claims	Meier References
	This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal.

The '496 Patent – Claims	Meier References
	If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is

The '496 Patent – Claims	Meier References
	overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the

The '496 Patent – Claims	Meier References
	node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED

The '496 Patent – Claims	Meier References
	LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing

The '496 Patent – Claims	Meier References
	table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a

The '496 Patent – Claims	Meier References
	DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state.

The '496 Patent – Claims	Meier References
	Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the

The '496 Patent – Claims	Meier References
	gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the

The '496 Patent – Claims	Meier References
	ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with

The '496 Patent – Claims	Meier References
	another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the

The '496 Patent – Claims	Meier References
	attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning

The '496 Patent – Claims	Meier References
	tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path.

The '496 Patent – Claims	Meier References
	4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
39. A method as recited in claim 37, wherein said first node process further includes:	"In alternate embodiments of the present invention, the RF Networks contain multiple gateways. By including a system identifier in the address field of the nodes, it is possible to determine which nodes are connected to which networks."

The '496 Patent – Claims	Meier References
determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	Moreover, it would have been obvious to implement authentication of clients and maintenance of a client link tree, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1: FIG. 1  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF

The '496 Patent – Claims	Meier References
	links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the

The '496 Patent – Claims	Meier References
	software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable

The '496 Patent – Claims	Meier References
	services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

The '496 Patent – Claims	Meier References
	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
receive information identifying selected transmission paths from each	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the

The '496 Patent – Claims	Meier References
of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by

The '496 Patent – Claims	Meier References
	monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the

The '496 Patent – Claims	Meier References
	data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the

The '496 Patent – Claims	Meier References
	packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must

The '496 Patent – Claims	Meier References
	remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and	"The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. maintain a client link tree having client link entries representing each of the plurality of client nodes.	the packet." Meier '436 at 6:66-7:11. "Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 7:6-11. "The end-to-end ATTACH.request functions as a discovery packet, and enables the root node to learn the address of the source node quickly." Meier '436 at 13:58-60. "All messages are routed along branches of the spanning tree. Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address)." Meier '436 at 14:36-42. "Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree…Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal." Meier '436 at 14:65-15:20.

The '496 Patent – Claims	Meier References
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	"Gateways are used to pass messages to and from a host computer and the RF Network. A host port is used to provide a link between the gateway and the host computer." Meier '436 at 2:26-28. "In one embodiment of the present invention, the RF data communication system has a host computer 10, a network controller 14 and bridges 22 and 24 attached to a data communication link 16. Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention." Meier '436 at 3:5-11.
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18.

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	"FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF

The '496 Patent – Claims	Meier References
	links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the

The '496 Patent – Claims	Meier References
	software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable

The '496 Patent – Claims	Meier References
	services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
wherein said client process of each of said clients initiates and selects a	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the

The '496 Patent – Claims	Meier References
radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45.

The '496 Patent – Claims	Meier References
	"If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO

The '496 Patent – Claims	Meier References
	packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node 20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by

The '496 Patent – Claims	Meier References
	monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11. "Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the

The '496 Patent – Claims	Meier References
	data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17. "Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the

The '496 Patent – Claims	Meier References
	packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal. IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must

Exhibit B4 – Invalidity Chart for Brownrigg Family based on the Meier references

The '496 Patent – Claims	Meier References
	remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node. 6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the

The '496 Patent – Claims	Meier References
	data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at

The '496 Patent – Claims	Meier References
	2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal

The '496 Patent – Claims	Meier References
	nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function. 3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer

The '496 Patent – Claims	Meier References
	A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"To initialize the RF data communication system, the gateway 20 and the other nodes are organized into an optimal spanning tree rooted at the gateway 20. To form the optimal spanning tree, in the preferred embodiment the gateway 20 is assigned a status of ATTACHED and all other bridges are assigned the status UNATTACHED. The gateway 20 is considered attached to the spanning tree because it is the root node. Initially, all other bridges are unattached and lack a parent in the spanning tree. At this point, the attached gateway node 20 periodically broadcasts a specific type of

The '496 Patent – Claims	Meier References
	polling packet referred to hereafter as 'HELLO packets'." Meier '436 at 3:56-68. "HELLO packets contain 1) the address of the sender, 2) the hopping distance that the sender is from the root, 3) a source address, 4) a count of nodes in the subtree which flow through that bridge, and 5) a list of system parameters." Meier '436 at 4:9-13. "Next, at a block 203, the bridge enters the UNATTACHED state, listening for HELLO packets (also referred to as HELLO messages herein) that are broadcast. By listening to the HELLO messages, bridges can learn which nodes are attached to the spanning tree. At a block 205, the bridge responds to a HELLO packet received by sending an ATTACH.request packet to the device that sent the received HELLO packet. The ATTACH.request packet is thereafter forwarded towards and to the root node which responds by sending an ATTACH.response packet back down towards and to the bridge." Meier '436 at 4:22-35. "The bridge awaits the ATTACH.response packet at a block 207. Upon receipt of the ATTACH.response packet, at a block 209, the bridge enters an ATTACHED state. Thereafter, at a block 211, the bridge begins periodically broadcasting HELLO packets and begins forwarding or relaying packets received. Specifically, between HELLO packet broadcasts, the bridge listens for HELLO, DATA, ATTACH.request and ATTACH.response packets broadcast by other devices in the communication network." Meier '436 at 4:36-45. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge

The '496 Patent – Claims	Meier References
	attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast." Meier '436 at 4:54-66. "Specifically, once attached, the attached bridge begins broadcasting HELLO packets (at the block 211) seeking to have all unattached bridges (or other network devices) attach to the attached bridge. Upon receiving an ATTACH.request packet, the bridge forwards that packet toward the root node (through the blocks 211, 213, 214 and 221. On its path toward the root, each node records the necessary information of how to reach requesting bridge. This process is called 'backward learning' herein, and is discussed more fully below." Meier '436 at 5:26-36. "Initially, only the root gateway node 20 is broadcasting HELLO messages and only nodes 40, 42 and 44 are within range of the HELLO messages broadcast by the gateway. Therefore, after the listening period has expired, nodes 40, 42 and 44 request attachment to the gateway node 20. The unattached nodes 40, 42, and 44 send ATTACH.request packets and the attached gateway node 20 acknowledges the ATTACH.request packets with local ATTACH.confirm packets. The newly attached bridges are assigned the status ATTACHED and begin broadcasting their own HELLO packets, looking for other unattached bridges. Again, the remaining unattached nodes attempt to attach to the attached nodes that are logically closest to the root node. For example, node 48 is within range of HELLO messages from both nodes 40 and 42. However, node 40 is three hops, via an RF link, away from the gateway root node 20 and node 42 is only one hop, via a hard-wired link, away from the gateway root node

The '496 Patent – Claims	Meier References
	20. Therefore, node 48 attaches to node 42, the closest node to the gateway root node 20." Meier '436 at 5:58-6:10. "Nodes, other than the gateway root node, after acknowledging an ATTACH.request packet from a previously unattached node, will send the ATTACH.request packet up the branches of the spanning tree to the gateway root node. As the ATTACH.request packet is being sent to the gateway root node, other nodes attached on the same branch record the destination of the newly attached node in their routing entry table. When the ATTACH.request packet reaches the gateway root node, the gateway root node returns an end-to-end ATTACH.confirm packet." Meier '436 at 6:27-37. "After the spanning tree is initialized, the RF terminals listen for periodically broadcasted Hello packets to determine which attached nodes are in range. After receiving HELLO messages from attached nodes, an RF terminal responding to an appropriate poll sends an ATTACH.request packet to attach to the node logically closest to the root." Meier '436 at 6:38-44. "The attached node acknowledges the ATTACH.request and sends the ATTACH.request packet to the gateway root node. Then, the gateway root node returns an end-to-end ATTACH.confirm packet. In this manner, the end-to-end ATTACH.request functions as a discovery packet enabling the gateway root node, and all other nodes along the same branch, to learn the address of the RF terminal quickly. This process is called backward learning. Nodes learn the addresses of terminals by monitoring the traffic from terminals to the root. If a packet arrives from a terminal that is not contained in the routing table of the node, an entry is made in the routing table. The entry includes the terminal address and the address of the node that sent the packet." Meier '436 at 6:66-7:11.

The '496 Patent – Claims	Meier References
	"Communication between terminals and the host computer is accomplished by using the resulting RF Network. To communicate with the host computer, an RF terminal sends a data packet in response to a poll from the bridge closest to the host computer. Typically, the RF terminal is attached to the bridge closest to the host computer. However, RF terminals are constantly listening for HELLO and polling messages from other bridges and may attach to, and then communicate with, a bridge in the table of bridges that is closer to the particular RF terminal." Meier '436 at 7:28-39. "When a bridge receives a data packet from a terminal directed to the host computer, the bridge forwards the data packet to the parent node on the branch. The parent node then forwards the data packet to its parent node. The forwarding of the data packet continues until the gateway root node receives the data packet and sends it to the host computer. Similarly, when a packet arrives at a node from the host computer directed to an RF terminal, the node checks its routing entry table and forwards the data packet to its child node which is along the branch destined for the RF terminal." Meier '436 at 7:55-65. "Communication is also possible between RF terminals. To communicate with another RF terminal, the RF terminal sends a data packet to its attached bridge. When the bridge receives the data packet from a terminal directed to the host computer, the bridge checks to see if the destination address of the RF terminal is located within its routing table. If it is, the bridge simply sends the message to the intended RF terminal. If not, the bridge forwards the data packet to its parent node. The forwarding of the data packet up the branch continues until a common parent between the RF terminals is found. Then, the common parent (often the gateway node itself) sends the data packet to the intended RF terminal via the branches of the RF Network." Meier '436 at 8:4-17.

The '496 Patent – Claims	Meier References
	"Base stations 'learn' the address of terminals by monitoring traffic from terminals (i.e., to the root). When a base station receives (i.e., an ATTACH.request) packet, destined for the root, the base station creates or updates an entry in its routing table for the terminal. The entry includes the terminal address, and the address of the base station which sent the packet (i.e., the hop address). When a base station receives an upstream packet (i.e., from the root, destined for a terminal) the packet is simply forwarded to the base station which is in the routing entry for the destination." Meier '436 at 14:37-48. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value.

The '496 Patent – Claims	Meier References
	If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "DELETING INVALID ROUTING TABLE ENTRIES is accomplished in several ways: connection oriented transport layer ensures that packets will arrive from nodes attached to the branch of the spanning tree within the timeout period, unless a node is disconnected.) 2) Whenever the DLC entity in a parent fails RETRY MAX times to send a message to a child node, the node is logically disconnected from the spanning tree, with one exception. If the child is a SLEEPING terminal, the message is retained by the network entity in the parent for "count" hello times. The parent immediately attempts to deliver the message after it sends its next hello packet. If, after "count" hello times, the message cannot be delivered, then the child is logically detached from the spanning tree. Detached node information is propagated downstream to the root node, each node in the path of the DETACH packet must adjust its routing tables appropriately according to the following rules: a) if the lost node is a child terminal node, the routing entry for the terminal is deleted and a DETACH packet is generated, b) if the node specified in DETACH packet is a terminal and the node which delivered the packet is the next hop in the path to the terminal, then the routing table entry for the terminal is deleted and the DETACH packet is forwarded, c) if the lost node is a child base station node then all routing entries which specify that base station as the next hop are deleted and a DETACH packet is generated for each lost terminal.

The '496 Patent – Claims	Meier References
	IN GENERAL, WHENEVER A NODE DISCOVERS THAT A TERMINAL IS DETACHED, IT PURGES ITS ROUTING ENTRY FOR THE TERMINAL. WHENEVER A NODE DISCOVERS THAT A BASE STATION IS DETACHED, IT PURGES ALL ROUTING ENTRIES CONTAINING THE BASE STATION. ONLY ENTRIES FOR UPSTREAM NODES ARE DELETED. When DETACH packets reach the root node, they are added to a "detached list." Nodes remain in the root node's detached list until a) the node reattaches to the spanning tree, or b) the list entry times out. The detached list is included in hello messages and is propagated throughout the spanning tree. For example, if a terminal detaches and reattaches to a different branch in the spanning tree, all downstream nodes in the new branch (quickly) "learn" the new path to the terminal. Nodes which were also in the old path change their routing tables and no longer forward packets along the old path. At least one node, the root, must be in both the old and new path. A new path is established as soon as an end-to-end attach request packet from the terminal reaches a node which was also in the old path. 4) A node (quickly) learns that it is detached whenever it receives a hello message, from any node, with its address in the associated detached list. The detached node can, optionally, send a global ATTACH.request, and then enters the UNATTACHED LISTEN state and reattaches as described above. After reattaching, the node must remain in a HOLD-DOWN state until its address is aged out of all detached lists. During the HOLD-DOWN state the node ignores detached lists. 5) A node becomes disconnected and enters the UNATTACHED LISTEN state whenever HELLO-RETRY-MAX hello messages are missed from its parent node.

The '496 Patent – Claims	Meier References
	6) A node enters the ATTACHED LISTEN state whenever a single hello message, from its parent, is missed. SLEEPING terminals remain awake during the ATTACHED LISTEN state. The state ends when the terminal receives a data or hello message from its parent. The terminal becomes UNATTACHED when a) its address appears in the detached list of a hello message from an ode other than its parent, or b) HELLO-RETRY-MAX hello messages are missed. The total number of hello slots spend in the LISTEN state is constant. If a node in the ATTACHED LISTEN state discovers a path to the root which is CHANGE-THRESHOLD shorter, it can attach to the shorter path. Periodically, SLEEPING terminals must enter the ATTACHED LEARN state to discovery any changes (i.e., shorter paths) in the network topology." Meier '436 at 14:59-16:6.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"An apparatus and a method for routing data in a radio data communication system having one or more host computers, one or more intermediate base stations, and one or more RF terminals organizes the intermediate base stations into an optimal spanning-tree network to control the routing of data to and from the RF terminals and the host computer efficiently and dynamically." Meier '436 at Abstract. "In such a system, communication from an RF terminal to a host computer may be achieved, for example, by having the RF terminal send data to an intermediate station, the intermediate station send the data to a base station, and the base station send the data directly to the host computer. Communicating with a host computer through more than one station is commonly known as a multiple-hop communication system." Meier at 1:66-2:6. "The present invention comprises an RF Local Area Network…" Meier '436 at 2:17-

The '496 Patent – Claims	Meier References
	18. "FIG. 1 is a functional block diagram of an RF data communication system incorporating the RF local-area network of the present invention." Meier '436 at 2:63-65. FIG. 1:  "Specifically, root of the spanning tree are the gateways; the branches are the bridges; and non-bridging stations, such as RF terminals, are the leaves of the tree. Data are sent along the branches of the newly created optimal spanning tree." Meier '436 at 2:44-48. "Also attached to the data communication link 16 is a gateway 20 which acts as the root node for the spanning tree of the RF data network of the present invention. A bridge 42 is attached to the gateway 20 through a hard-wired communication link

The '496 Patent – Claims	Meier References
	and bridges 40 and 44 are logically attached to gateway 20 by two independent RF links. Additional bridges 46, 48, 50 and 52 are also connected to the RF Network and are shown in the FIG. 1. Note that, although shown separate from the host computer 10, the gateway 20 (the spanning tree root node) may be part of host computer 10." Meier '436 at 3:9-19. "In the preferred embodiment, the host computer 10 is an IBM 3090, the network controller 14 is a model RC3250 of the Norand Corporation, the data communication link 16 is an Ethernet link, the nodes 20, 22, 24, 40, 42, 44, 46, 48, 50 and 52 are intelligent base transceiver units of the type RB4000 of the Norand Corporation, and the RF terminals 100, 102, 104, 106, 108, 110, 112, 114, 116, 118 and 120 are of type RT1100 of the Norand Corporation." Meier '436 at 3:40-48. "Devices in the spanning tree are logically categorized as one of the following three node types: 1) Root (or root bridge)--A controller device which functions as the root bridge of the network spanning tree. In the preferred embodiment, the spanning tree has a single root node. Initially, all controllers are root candidates from which a root node is selected. This selection may be based on the hopping distance to the host, preset priority, random selection, etc. 2) Bridge--An internal node in the spanning tree which is used to "bridge" terminal nodes together into an interconnected network. The root node is also considered a bridge and the term "bridge" may be used to refer to all non-terminal nodes or all non-terminal nodes except the root, depending on the context herein. A bridge node consists of a network interface function and a routing function.

The '496 Patent – Claims	Meier References
	3) Terminal--leaf node in the spanning tree. A terminal node can be viewed as the software entity that terminates a branch in the spanning tree." Meier '436 at 9:16-43. "A controller device contains a terminal node(s) and a bridge node. The bridge node is the root node if the controller is functioning as the root bridge. A base station contains a bridge node. A terminal device contains a terminal node and must have a network interface function. A 'bridging entity' refers to a bridge node or to the network interface function in a terminal." Meier '436 at 9:37-43. "The software for the spread-spectrum system is functionally layered as follows. Medium Access Control (MAC) The MAC layer is responsible for providing reliable transmission between any two nodes in the network (i.e. terminal-to-bridge). The MAC has a channel access control component and a link control component. The link control component facilitates and regulates point-to-point frame transfers in the absence of collision detection. The MAC channel access control component regulates access to the network. Note that herein, the MAC layer is also referred to as the Data Link layer." Meier '436 at 9:60-10:3. "Logical Link Control Layer A logical link control layer, also known herein as the Transport layer herein, is responsible for providing reliable transmission between any two nodes in the network (i.e., terminal-to-base station). The data-link layer provides a connection-oriented reliable service and a connectionless unreliable service. The reliable service

The '496 Patent – Claims	Meier References
	detects and discards duplicate packets and retransmits lost packets. The unreliable services provides a datagram facility for upper layer protocols which provide a reliable end-to-end data path. The data-link layer provides ISO layer 2 services for terminal-to-host application sessions which run on top of an end-to-end terminal-to-host transport protocol. However, the data-link layer provides transport (ISO layer 4) services for sessions contained within the SST network." Meier '436 at 10:29-44. "If at the block 213 detachment has not occurred, at a block 214, the bridge determines if the received packet is a HELLO packet. If so, the bridge analyzes the contents of the HELLO packet at a block 215 to determine whether to change its attachment point in the spanning tree. In a preferred embodiment, the bridge attempts to maintain attachment to the spanning tree at the node that is logically closest to the root node. The logical distance, in a preferred embodiment, is based upon the number of hops needed to reach the root node and the bandwidth of those hops. The distance the attached node is away from the root node is found in the second field of the HELLO message that is broadcast. In another embodiment of the present invention, the bridges consider the number of nodes attached to the attached node as well as the logical distance of the attached node from the root node. If an attached node is overloaded with other attached nodes, the unattached bridge may request attachment to the less loaded node, or to a more loaded node as described above in networks having regions of substantial RF overlap. In yet another embodiment, to avoid instability in the spanning tree, the bridge would only conclude to change attachment if the logical distance of the potential replacement is greater than a threshold value. If no change in attachment is concluded, at a block 217 the bridge branches back to the block 211. If a determination is made to change attachment, a DETACH packet is

The '496 Patent – Claims	Meier References
	sent to the root as illustrated at a block 219. After sending the DETACH packet, the bridge branches back to the block 205 to attach to the new spanning tree node. Note that the order of shown for detachment and attachment is only illustrative and can be reversed." Meier '436 at 4:54-5:19. "The interfaces to the next upper (i.e., application) layer include: CONNECT (access.sub.-- point, node.sub.-- name) LISTEN (access.sub.-- point) UNITDATA (access.sub.-- point, node.sub.-- name, buffer, length) SEND (handle, buffer, length) RECEIVE (handle, buffer, length) CLOSE (handle) The 'handle' designates the connection type, and is the connection identifier for TCP-like connections." Meier '436 at 16:63-17:5. U.S. Patent No. 5,940,771 (Gollnick) at Figure 7 "shows a block diagram of a particularly preferred intelligent base transceiver unit known as the RB4000." Gollnick at 11:37-38 ("RF Base Intelligent Controller (7-70)"; "Base Radio Transceiver SST or UHF (701)").
dynamically updating a second node	"The attached node acknowledges the ATTACH.request and sends the

	to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17.

The '516 Patent – Claims	Dynamic Source Routing References
	"In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3.

The '516 Patent – Claims	Dynamic Source Routing References
	"A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7.

The '516 Patent – Claims	Dynamic Source Routing References
	"Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet,

The '516 Patent – Claims	Dynamic Source Routing References
	reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing

The '516 Patent – Claims	Dynamic Source Routing References
	it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply

The '516 Patent – Claims	Dynamic Source Routing References
	is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the

The '516 Patent – Claims	Dynamic Source Routing References
more of other clients of said first network;	other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to

The '516 Patent – Claims	Dynamic Source Routing References
	accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other

The '516 Patent – Claims	Dynamic Source Routing References
	packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized

The '516 Patent – Claims	Dynamic Source Routing References
transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Stations having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '516 Patent – Claims	Dynamic Source Routing References
by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '516 Patent – Claims	Dynamic Source Routing References
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4.

The '516 Patent – Claims	Dynamic Source Routing References
	"In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate

The '516 Patent – Claims	Dynamic Source Routing References
	route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
11. A method as recited in claim 10:	It would have been obvious for a node in the ad hoc network to serve as a gateway to,

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '516 Patent – Claims	Dynamic Source Routing References
wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '516 Patent – Claims	Dynamic Source Routing References
	host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this

The '516 Patent – Claims	Dynamic Source Routing References
	packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be

The '516 Patent – Claims	Dynamic Source Routing References
	shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients.	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Dynamic Source Routing References
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson

The '314 Patent – Claims	Dynamic Source Routing References
	1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1.

The '314 Patent – Claims	Dynamic Source Routing References
	"[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then

The '314 Patent – Claims	Dynamic Source Routing References
	transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each

The '314 Patent – Claims	Dynamic Source Routing References
	forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154.

The '314 Patent – Claims	Dynamic Source Routing References
	"In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record

The '314 Patent – Claims	Dynamic Source Routing References
	from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving

The '314 Patent – Claims	Dynamic Source Routing References
	(very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the

The '314 Patent – Claims	Dynamic Source Routing References
	sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future

The '314 Patent – Claims	Dynamic Source Routing References
	packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme,

The '314 Patent – Claims	Dynamic Source Routing References
	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. The '314 Patent – Claims	Dynamic Source Routing References
	in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson

The '314 Patent – Claims	Dynamic Source Routing References
	and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary

	when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches."

The '314 Patent – Claims	Dynamic Source Routing References
	Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the

The '314 Patent – Claims	Dynamic Source Routing References
	packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Mobile Computing at 159. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme,

The '314 Patent – Claims	Dynamic Source Routing References
	as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Mobile Computing at 157. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. 	"Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the

The '314 Patent – Claims	Dynamic Source Routing References
	interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then

The '314 Patent – Claims	Dynamic Source Routing References
	sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more

The '314 Patent – Claims	Dynamic Source Routing References
	frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '314 Patent – Claims	Dynamic Source Routing References
said first network to said first node can be through one or more of other second node of said first network;	new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '314 Patent – Claims	Dynamic Source Routing References
	closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the

The '314 Patent – Claims	Dynamic Source Routing References
	route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination

The '314 Patent – Claims	Dynamic Source Routing References
	of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2.

The '314 Patent – Claims	Dynamic Source Routing References
	"Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the

The '314 Patent – Claims	Dynamic Source Routing References
	target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

The '314 Patent – Claims	Dynamic Source Routing References
	"While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169.

The '314 Patent – Claims	Dynamic Source Routing References
	"We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned,

The '314 Patent – Claims	Dynamic Source Routing References
	or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.

Exhibit B5 – Invalidity Chart for Brownrigg Family based on the Dynamic Source Routing References

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Dynamic Source Routing References
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson

The '471 Patent – Claims	Dynamic Source Routing References
	1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. 	sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165. It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future

The '471 Patent – Claims	Dynamic Source Routing References
	packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining] the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissions in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme,

The '471 Patent – Claims	Dynamic Source Routing References
	packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Mobile Computing at 155. "Each mobile host participating in the ad hoc network maintains a route cache in which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Mobile Computing at 158. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further includes logic that maintains a client	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing

link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	It would have been obvious for a person of ordinary skill in the art to optimize the route cache stored in each node of ad hoc network of the Dynamic Source Routing references in order to provide an efficient and reliable path to other nodes in the ad hoc network. Further, it would have been obvious for a node to provide the optimized route cache to other nodes so that other nodes, especially nodes joining the ad hoc network could quickly learn efficient source routes.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no

The '471 Patent – Claims	Dynamic Source Routing References
current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	new route discovery is needed for this mobile host to communicate with any of the other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is

The '471 Patent – Claims	Dynamic Source Routing References
	desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163.

Mobile Computing at 166-67.
4. A wireless network system as	It would have been obvious to implement authentication of clients and maintenance

The '471 Patent – Claims	Dynamic Source Routing References
recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	of a client link tree. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Suppose, in Figure 4, that none of these optimizations for handling errors are in use. When A receives B's route error packet, it may initiate a route discovery in order to find a new route to the same target. However, if hosts C, D, or E have an entry in their route cache for this target, they will likely reply to A from their cache with a cached copy of the same route that A just removed from its cache. If instead, A could enter into its cache when it receives B's route error packet, an indication that this hop is not currently working (rather than simply removing this hop from any routes currently in its cache), then A could ignore future replies from C, D, and E that include this hop from their caches." Johnson and Maltz at 11. "A last optimization to improve the handling of errors is to support the caching of 'negative' information in a host's route cache. Mobile Computing at 168.
6. A wireless network system comprising:	"An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any centralized administration or standard support

The '471 Patent – Claims	Dynamic Source Routing References
a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	services." Johnson 1994, Abstract. "Mobile hosts such as notebook computers, featuring powerful CPUs, large main memories, hundreds of megabytes of disk space, multimedia sound capabilities, and color displays, are now easily affordable and are becoming quite common in everyday business and personal life." Johnson 1994 at 1. "[E]mployees may find themselves together in a meeting room; friends or business associates may run into each other in an airport terminal; or a collection of computer science researchers may gather in a hotel ballroom for a workshop or conference. Requiring each user to connect to a wide-area network in such situations, only to communicate with each other, may not be possible due to lack of facilities, or may be inconvenient or impractical due to the time or expense required for such connection." Johnson 1994 at 1. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 "In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination. As long as conditions remain unchanged, this route should then continue to work for as long as it is needed. However, as the status of different links or routers used in this route change, changes in the route may be necessary, or a new route may need to be discovered" Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4.

The '471 Patent – Claims	Dynamic Source Routing References
	"We are also exploring additional areas related to ad hoc networking, such as the routing between an ad hoc network and wide-area network such as the Internet: if one or more of the mobile hosts in an ad hoc network are also connected to the Internet [8], it is possible for other mobile hosts in the ad hoc network to communicate with Internet hosts, but additional routing support is needed…" Johnson at 5. "[W]hen opening a TCP connection, separate packets are usually used to exchange SYN and ACK control bits between the two end hosts of the connection."); Johnson 1994 at 3 ("it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 4. "In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson at 4. "[I]t must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "Dynamic Source Routing in Ad Hoc Wireless Networks." Johnson and Maltz at 1. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Johnson and Maltz at 1. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an

The '471 Patent – Claims	Dynamic Source Routing References
	earthquake or flood." Johnson and Maltz at 1. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Johnson and Maltz at 9. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Johnson and Maltz at 11 "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Johnson and Maltz at 17. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 17. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet

The '471 Patent – Claims	Dynamic Source Routing References
	is delivered to the network layer software on that host." Johnson and Maltz at 4. "The route request thus propagates through the ad hoc network until it reaches the target host, which then replies to the initiator. The original route request packet is received only by those hosts within wireless transmission range of the initiating host, and each of these hosts propagates the request if it is not the target and if the request does not appear to this host to be redundant." Johnson and Maltz at 5. "We refer to the number of hops necessary for a packet to reach from any host located at one extreme edge of the network to another host located at the opposite extreme, as the diameter of the network. For example, the diameter of the ad hoc network depicted in Figure 1 is two. We assume that the diameter of an ad hoc network will be small but may often be greater than one." Johnson and Maltz at 3. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "This paper describes the design and performance of a routing protocol for ad hoc networks that instead uses dynamic source routing of packets between hosts that want to communicate. Source routing is a routing technique in which the sender of a packet determines the complete sequence of nodes through which to forward the packet; the sender explicitly lists this route in the packet's header, identifying each forwarding 'hop' by the address of the next node to which to transmit the packet on its way to the destination host." Johnson and Maltz at 2. "Each mobile host participating in the ad hoc network maintains a route cache in

The '471 Patent – Claims	Dynamic Source Routing References
	which it caches source routes that it has learned. When one host sends a packet to another host, the sender first checks its route cache for a source route to the destination. If a route is found, the sender uses this route to transmit the packet." Johnson and Maltz at 4. "Figure 2 shows an ad hoc network of five mobile hosts, in which mobile host A has earlier completed a route discovery for mobile host D and has cached the route to D through B and C. Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Johnson and Maltz at 7. "Dynamic Source Routing in Ad Hoc Wireless Networks." Mobile Computing at 153. "An ad hoc network is a collection of wireless mobile hosts forming a temporary network without the aid of any established infrastructure or centralized administration." Mobile Computing at 153. "[A] class of students may need to interact during a lecture, friends or business associates may run into each other in an airport terminal and wish to share files, or a group of emergency rescue workers may need to be quickly deployed after an earthquake or flood." Mobile Computing at 154. "In order to return the route reply packet to the initiator of the route discovery, the target host must have a route to the initiator. If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route

The '471 Patent – Claims	Dynamic Source Routing References
	in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Mobile Computing at 160. "While two hosts are communicating with each other using cached routes, it is

The '471 Patent – Claims	Dynamic Source Routing References
	desirable for the hosts to begin using shorter routes if the hosts move suffciently closer together. In many cases, the basic route maintenance procedure is sufficient to accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Mobile Computing at 166. "An improvement to this method of refiecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Mobile Computing at 166-67. "[S]mall data packets such as the initial SYN packet opening a TCP connection [23] could also easily be piggybacked, but we have not yet experimented with this option." Mobile Computing at 165. "[T]hey could also represent a number of cars with radio-equipped portables driving (very quickly) around an area of 1 square kilometer." Mobile Computing at 169. "We are also continuing to study other routing protocols for use in ad hoc networks, including those based on distance vector or link state routing, as well as the

The '471 Patent – Claims	Dynamic Source Routing References
	interconnection of an ad hoc network with a wide-area network such as the Internet, reachable by some but not all of the ad hoc network nodes." Mobile Computing at 178. "To send a packet to another host, the sender constructs a source route in the packet's header, giving the address of each host in the network through which the packet should be forwarded in order to reach the destination host. The sender then transmits the packet over its wireless network interface to the first hop identified in the source route. When a host receives a packet, if this host is not the final destination of the packet, it simply transmits the packet to the next hop identified in the source route in the packet's header. Once the packet reaches its final destination, the packet is delivered to the network layer software on that host." Mobile Computing at 157-58. "If the host attempts to send additional data packets to this same host more frequently than this limit, the subsequent packets may be buffered until a route reply is received, but they do not initiate a new route discovery until the minimum allowable interval between new route discoveries for this target has been reached." Mobile Computing at 167. "Another option in the case of returning a route error packet is for this host to save the route error packet locally in a buffer, perform a route discovery for the original sender, and then send the route error packet using that route when it receives the route reply for this route discovery." Mobile Computing at 161. "As described in Section 3.2, when one host needs to send a packet to another, if the sender does not have a route cached to the destination host, it must initiate a separate route discovery, either buffering the original packet until the route reply is returned, or discarding it and relying on a higher-layer protocol to retransmit it if needed." Mobile Computing at 165.

The '471 Patent – Claims	Dynamic Source Routing References
	It would have been obvious for a node in the ad hoc network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In order for one host to communicate with another, it must initially discover a suitable route to use in sending packets to that destination." Johnson 1994 at 3. "[I]f the source and target mobile hosts are both within transmission range of each other, a simple ARP query is all that is needed to find a 'route' to the target host." Johnson 1994 at 3. "As the request propagates, each host adds its own address to a route being recorded in the packet, before broadcasting the request on to its neighbors." Johnson 1994 at 3. "When the query packet ultimately reaches the target host, the complete route from the original sender to this host will have been recorded in the packet. In order to be of use to the original sender, though, the route must then be returned to the sender." Johnson 1994 at 4. "Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination." Johnson 1994 at 4. "Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing [sic, examining]

Since hosts B and C are on the route to JD, host A also learns the route to both of these hosts from its route discovery for D. If A later performs a route discovery and learns the route to E through B and C, it can represent this in its route cache with the addition of the single new hop from C to E. If A then learns it can reach C in a single hop (without needing to go through B), A can use this new route to C to also shorten the routes to D and E in its route cache." Mobile Computing at 162-63.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"Mobile hosts should cache routes discovered in this way for use in sending future packets to that same destination. The overhead of the protocol can be further reduced by making more extensive use of such caching. If a mobile host has cached a route listing some number of hops to a destination mobile host, then the shortest route to each of the hops listed on that route is naturally a prefix of that route. In this case, no new route discovery is needed for this mobile host to communicate with any of the

The '471 Patent – Claims	Dynamic Source Routing References
	other mobile hosts named as hops on any of the routes currently in its cache. Also, as a mobile host forwards packets, it will be able to observe many other routes to other mobile hosts, since each packet contains a route. By examing the routes on packets that it forwards, a mobile host may be able to cache routes to new destinations or to obtain updated information to destinations already in its cache. Furthermore, since transmissioins in a wireless network are necessarily broadcast transmissions, a mobile host may be able to learn new routing information from the route contained in any packet that it can receive, even if the packet is not explicitly addressed to this host." Johnson 1994 at 4. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Johnson and Maltz at 7. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Johnson and Maltz at 7. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other packet (Section 3.1). Otherwise, the target may reverse the route in the route record from the route request packet, and use this route to send the route reply packet." Johnson and Maltz at 5. "While two hosts are communicating with each other using cached routes, it is desirable for the hosts to begin using shorter routes if the hosts move sufficiently closer together. In many cases, the basic route maintenance procedure is sufficient to

The '471 Patent – Claims	Dynamic Source Routing References
	accomplish this, since if one of the hosts moves enough to allow the route to be shortened, it will likely also move out of transmission range of the first hop on the existing route." Johnson and Maltz at 9. "An improvement to this method of reflecting shorter routes is possible if hosts operate their network interfaces in promiscuous receive mode. Suppose somewhere in the forwarding of a packet, mobile host B transmits a packet to C, with D being the next hop after C in the route in the packet, as illustrated in Figure 3. If D receives this packet, it can examine the packet header to see that the packet reached it from B in one hop rather than two as intended by the route in the packet. In this case, D may infer that route may be shortened to exclude the intermediate hop through C. D then sends an unsolicited route reply packet to the original sender of the packet, informing it that it can now reach D in one hop from B. As with other route reply packets, other hosts which also receive this route reply (in particular, other hosts also operating in promiscuous receive mode) may also incorporate this change into their route caches." Johnson and Maltz at 9. "The data in a host's route cache may be stored in any format, but the active routes in its cache in effect form a tree of routes, rooted at this host, to other hosts in the ad hoc network." Mobile Computing at 162. "A host can add entries to its route cache any time it learns a new route. In particular, when a host forwards a data packet as an intermediate hop on the route in that packet, the forwarding host is able to observe the entire route in the packet." Mobile Computing at 163. "If the target has an entry for this destination in its route cache, then it may send the route reply packet using this route in the same way as is used in sending any other
