wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. ""When a packet is to be transmitted, the processor activates a DMA channel to control and monitor the transmission. Under DMA control, the packet is read from the processor memory, convolutionally encoded with a constraint length 24 code, and loaded into a buffer prior to scrambling (bit order permutation). The packet data is read from the buffer bit by bit in pseudo random order, differentially encoded, and passed to the spread spectrum modulator where each data bit is modulo two added to each chip of the PN chip sequence used to encode that bit. …Fig. 15 shows the basic UPR packet and preamble format. In the discussion above, only the header and text bits of the packet are read from the processor memory. The preamble and postamble bits are supplied by the code generator circuitry, and are used in combination by the receiver to determine the receive data rate and coding format of the packet." "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been

	obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device.

	It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets:

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the

	nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby

	repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477. Figure 9, Kahn page 1480. "The location of the major elements of the packet radio testing during 1977 is shown in Fig. 12." Kahn page 1488. Figure 12, Kahn page 1489.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures." Kahn page 1479. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-point routing information? One possibility is for it to distribute the information to the individual repeaters along the

	point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header." Kahn page 1479. Figure 8, Kahn page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for

	routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service

	module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "H. Error Control Data integrity is crucial for most computer applications. Error

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Kahn

	control should be provided by the network, so that packets delivered to a user with undetected errors occur less frequently than about one in 1010 packets. …While detection of errors is essential, choices exist in dealing with the detected errors. In some cases, error detection and retransmission may be used, while in other environments, more sophisticated forward error correction technology must be used in order to maintain satisfactory throughput and delay when communicating through land mobile radio channels." Kahn page 1470. "For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. "The error control bits consist of a checksum appended by the transmitter and checked by each receiver." Kahn page 1479. Figure 8, Kahn page 1479.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information over a wide geographic area." Kahn Abstract.
a transceiver configured to send and receive wireless communications; and	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section

	which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	Figure 6, Kahn page 1478. "An individual packet radio is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections area connected by a high speed interface (see Fig. 6)." Kahn page 1477. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host

	computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin

	page 25-26. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be

	programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A

	tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "1) TIU measurement software-provides sources and sinks of controlled traffic streams; generates and collects pickup packets; received, collects end-device CUMSTATS; and periodically sends collected data to station measurement process. … 2) PRU measurement software-collects subnet CUMSTATS and

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Kahn

	snapshots; enters local data into pickup packets; and periodically sends collected data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms. 3) Station measurement software- controls experiments and collects the resulting measurement data." Kahn page 1495.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference. "From the station, parameters in each PR and terminal device in

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Kahn

	the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures." Kahn page 1479.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information over a wide geographic area." Kahn Abstract.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network

	routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477. "For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. "Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479. Figure 8, Kahn page 1479. Figure 9, Kahn page 1480. Figure 12, Kahn page 1489.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	Figure 6, Kahn page 1478. "An individual packet radio is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the

	antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections area connected by a high speed interface (see Fig. 6)." Kahn page 1477.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	"For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. "Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479. Figure 8, Kahn page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET,

	discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number,

	and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the

	monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "1) TIU measurement software-provides sources and sinks of

	controlled traffic streams; generates and collects pickup packets; received, collects end-device CUMSTATS; and periodically sends collected data to station measurement process. … 2) PRU measurement software-collects subnet CUMSTATS and snapshots; enters local data into pickup packets; and periodically sends collected data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms. 3) Station measurement software- controls experiments and collects the resulting measurement data." Kahn page 1495.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "1) TIU measurement software-provides sources and sinks of controlled traffic streams; generates and collects pickup packets; received, collects end-device CUMSTATS; and periodically sends collected data to station measurement process. … 2) PRU measurement software-collects subnet CUMSTATS and snapshots; enters local data into pickup packets; and periodically sends collected data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms. 3) Station measurement software- controls experiments and collects the resulting measurement data." Kahn page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional

	references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. 25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information over a wide geographic area." Kahn Abstract.
a transceiver configured to send and receive wireless communications; and	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure

	described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477. "For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. "Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479. Figure 8, Kahn page 1479. Figure 9, Kahn page 1480. Figure 12, Kahn page 1489.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	Figure 6, Kahn page 1478. "An individual packet radio is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections area connected by a high speed interface (see Fig. 6)." Kahn page 1477.

	"For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. "Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479. Figure 8, Kahn page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter

	memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Similarly, Burchfiel, which is also directed to the PRNET,

	discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command

	station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first,

	broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a

	network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing

	explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

The '661 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

with a wide area network (WAN);	cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "The initial ARPA program objective was to develop a geographically

	distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

	measurement file located at the station." Kahn, p. 1495. "At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.  (b) **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.

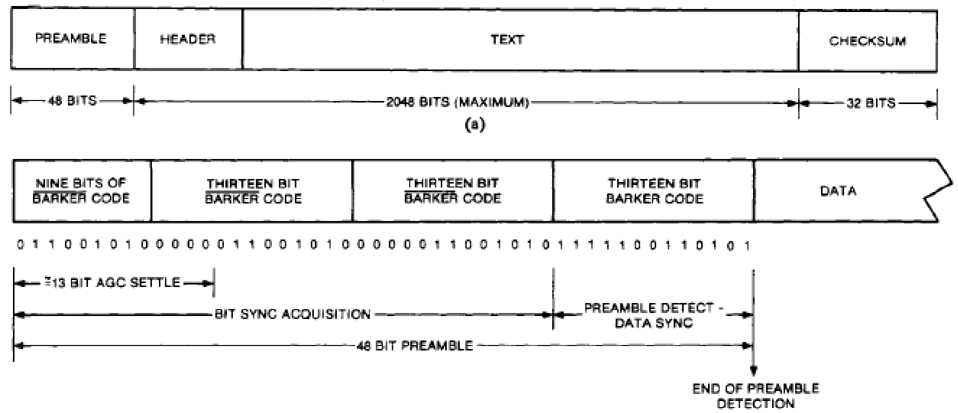
Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

5. A system for monitoring remote devices, comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495.

	"Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495. "At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495. "I) TIU measurement software-provides sources and sinks of controlled traffic streams; generates and collects pickup packets; collects end-device CUMST ATS; and periodically sends collected data to station measurement process. End-device cumstats collected consist of packet activity counters, retransmission histograms, and end-to-end acknowledgment time delay spectra." "2) PRU measurement software-collects subnet CUMSTATS and snapshots; enters local data into pickup packets; and periodically sends collected data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms." Kahn, p. 1495.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. Figure 13, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

	1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.



(b)

Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.

one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477.

	"For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. Figure 13, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the

	collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
9. A system for controlling a remote device comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to

	the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a target remote device having an actuator to be controlled;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that generates at least one control	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network

signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page

	247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and

	that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

a gateway connected to the WAN configured to receive and translate the at least one control signal	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. Figure 13, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,468,661 based on KAHN

	the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.  (b) **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.**
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent

	No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more

	monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination." Kahn page 1479. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination." Kahn page 1479. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469.

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a plurality of non-earth orbiting transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible

predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. Figure 13, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487

	"While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." 	Kahn page 1493.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 12 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

The '692 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. A system for remote data collection, assembly, and storage comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

with a wide area network (WAN);	cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477.

	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495.

	"Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.  **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn

	page 1468. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479.

	"An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495. "At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

	 **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and

	demodulation." Kahn page 1477. Figure 6, Kahn page 1478. Figure 13, Kahn page 1489.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. "1) Network Management and Control: A centralized network management facility (NMF) has been developed for managing and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated." Kahn p[age 1494. "The four primary measurement tools that have been developed are: cumulative statistics (CUMSTATS), snapshots, pickup packets, and neighbor tables, CUMSTATS consist of a variety of activity counters in each node. Snapshots periodically record the disposition of packet buffers and other node resources. Pickup packets are "crates" that start out empty at a traffic source, and pick up information at each node they traverse en route to their destination, thus providing a trace of their history. Neighbor tables are a table of counts of packets received from each "neighbor" PR in range." Kahn page 1495.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select	The above contentions for claim 1 are hereby incorporated by reference. "In a packet-switched network, the unit of transmission is called a packet. It

information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "A packet of some appropriate size is also a natural unit of communication for computers. Processors store, manipulate, and transfer data in finite length segments, as opposed to indefinite length streams. It is therefor natural that these internal segments correspond to the computer generated packets, although a segment could be sent as a sequence of one or more packets." Kahn page 1468. "E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet and, at most only a small finite set of them could be carried along." Kahn page 1479.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a user may select based on his application." Kahn page 1469. "We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts." Kahn page 1469. "We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the

	system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.

7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. "The functions of a station are associated with global management of the radio net [24]. Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. …One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR's and using the information to assign good routes." Kahn page 1477. Figure 12, Kahn page 1489.
8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. "A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a user may select based on his application." Kahn page 1469.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

	"We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.
11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"Functions provided within station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn page 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols o access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.

12. The system as defined in claim 1, wherein the gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	The above contentions for claim 1 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 Burchfiel discloses: "When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16.

	'650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses:

	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols o access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. 24. A method for controlling a system comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
remotely collecting data from at least one sensor;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

	"“The four primary measurement tools that have been developed are: cumulative statistics (CUMSTATS), snapshots, pickup packets, and neighbor tables, CUMSTATS consist of a variety of activity counters in each node. Snapshots periodically record the disposition of packet buffers and other node resources. Pickup packets are "crates" that start out empty at a traffic source, and pick up information at each node they traverse en route to their destination, thus providing a trace of their history. Neighbor tables are a table of counts of packets received from each "neighbor" PR in range." Kahn page 1495.
processing the data into a radio-frequency (RF) signal;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477.
transmitting the RF signal, via a relatively low-power transceiver, to a gateway;	"The functions of a station are associated with global management of the radio net [24]. Generally speaking, each station is aware of all operational radios in the network. The stations discover the existence of new radios waiting to enter the net and determine when other radios have departed. …One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR's and using the information to assign good routes." Kahn page 1477. Figure 12, Kahn page 1489.
translating the data in the RF signal into a network transfer protocol;	The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

	internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by the at least one sensor by generating an appropriate control signal;	"The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn page 1494.
sending the control signal via the network to the gateway,	The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.
translating the control signal from a network transfer protocol into an RF control signal;	"By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.
transmitting the RF control signal;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
receiving the RF control signal;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
translating the received RF control signal into an analog signal; and	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477.

applying the analog signal to an actuator to effect the desired system response.	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
25. The method of claim 24, wherein the RF signal contains a concatenation of information comprising encoded data information and transmitter identification information from an originating transmitter.	The above contentions for claim 24 are hereby incorporated by reference. "In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "A packet of some appropriate size is also a natural unit of communication for computers. Processors store, manipulate, and transfer data in finite length segments, as opposed to indefinite length streams. It is therefor natural that these internal segments correspond to the computer generated packets, although a segment could be sent as a sequence of one or more packets." Kahn page 1468. "E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this

	case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet and, at most only a small finite set of them could be carried along." Kahn page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
26. The method of claim 25, wherein the step of transmitting the RF signal is further performed by at least one transceiver, wherein the transceiver is configured to concatenate a transceiver identification code to the RF signal.	The above contentions for claim 25 are hereby incorporated by reference. "Regardless of how the routing entries are finally created within the repeaters along the point-to-point route, it may still be desirable to carry along within each data packet the selector for the next downstream repeater, or even the next few repeaters. The latter strategy may have significant operational as well as performance advantages as is discussed further in Section V." Kahn page 1479.
27. The method of claim 25, wherein the step of	The above contentions for claim 25 are hereby incorporated by reference.

transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	"“E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet and, at most only a small finite set of them could be carried along." Kahn page 1479." Figure 9, Kahn page 1480. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

28. The method of claim 25, wherein the steps of translating and applying the received RF control signal are performed only by an identified transceiver electrically integrated with an actuator.	The above contentions for claim 25 are hereby incorporated by reference. "The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station." Kahn page 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols o access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
30. The method of claim 25, wherein the network is an Intranet.	The above contentions for claim 1 are hereby incorporated by reference. "At the present time, two packet radio experimental networks are operating: an experimental testbed network covering much of the San Francisco Bay Area; and a local distribution network in the Boston Area, which is used for station software development." Kahn page 1494. "The user's terminal interface unit (TIU) also supports both formed of remote

	debugging. This feature has proven essential to the Bay Area PRNET development in that station software developers located in Boston and packet radio software developers in Texas can remotely participate in network debugging as the need arises, and new software versions can be conveniently installed from remote development sites as frequently as required." Kahn page 1494.
31. The method of claim 25, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 25 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard

	internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. 	Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
32. A system for monitoring remote devices comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of

	interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"1) Network Management and Control: A centralized network management facility (NMF) has been developed for managing and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated." Kahn p[age 1494. "The four primary measurement tools that have been developed are: cumulative statistics (CUMSTATS), snapshots, pickup packets, and neighbor tables, CUMSTATS consist of a variety of activity counters in each node. Snapshots periodically record the disposition of packet buffers and other node resources. Pickup packets are "crates" that start out empty at a traffic source, and pick up information at each node they traverse en route to their destination, thus providing a trace of their history. Neighbor tables are a table of counts of packets received from each "neighbor" PR in range." Kahn page 1495.
at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a	"In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn

low-power radio-frequency (RF) signal;	page 1468. “We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight.” Kahn, p. 1477. “For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios.” Kahn, p. 1477. “An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation.” Kahn page 1477. Figure 6, Kahn page 1478. “Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range.” Kahn, p. 1481. “Each radio has an identifier which we shall call its selector.” Kahn, p. 1479. “For the purposes of this paper, we assume the selectors are unique for clarity

	in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.

	 (b) **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479
at least one gateway connected a wide area network (WAN) configured to receive and translate the RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"The functions of a station are associated with global management of the radio net [24]." Kahn page 1477. "Functions provided within station software installed in 1977 included: network routing control; a gateway to other networks; a network measurement facility which collects, stores, and delivers experimental statistics from any network components; a debugging facility which supports examining and depositing the contents of memory in the PR units; an information service which assists in locating and connecting to people currently using the PRNET; and an experiment configuration control module." Kahn page 1488. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to

	access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478.

36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	The above contentions for claim 32 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page

	22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP)

	signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.

	The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . 38. The system defined in claim 32, wherein the WAN is a dedicated Intranet.	The above contentions for claim 32 are hereby incorporated by reference. "At the present time, two packet radio experimental networks are operating: an experimental testbed network covering much of the San Francisco Bay Area; and a local distribution network in the Boston Area, which is used for station software development." Kahn page 1494. "The user's terminal interface unit (TIU) also supports both formed of remote debugging. This feature has proven essential to the Bay Area PRNET development in that station software developers located in Boston and packet

	radio software developers in Texas can remotely participate in network debugging as the need arises, and new software versions can be conveniently installed from remote development sites as frequently as required." Kahn page 1494.
42. A system for controlling remote devices comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that generates at least one control	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network

signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters,

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

	receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487

	"While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.

	 **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479 "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "A packet of some appropriate size is also a natural unit of communication for computers. Processors store, manipulate, and transfer data in finite length segments, as opposed to indefinite length streams. It is therefor natural that these internal segments correspond to the computer generated packets, although a segment could be sent as a sequence of one or more packets." Kahn page 1468. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input into the digital section of his packet radio, which ads some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn page 1477. "E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the

point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet and, at most only a small finite set of them could be carried along." Kahn page 1479.

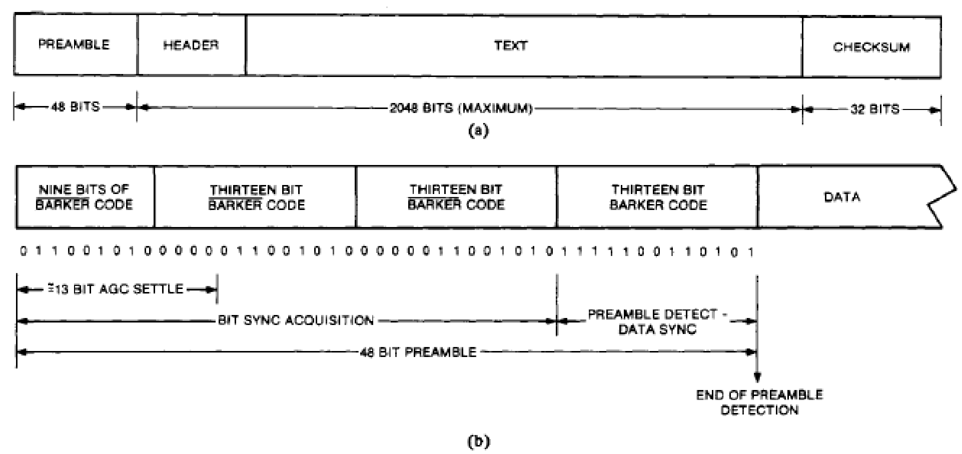

Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.

Kahn page 1479.

To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of

	one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet

	System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses:

	"The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses:

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
47. The system defined in claim 42, wherein the WAN is the Internet.	The above contentions for claim 42 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. '817 patent, 6:1-8.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. "At the present time, two packet radio experimental networks are operating: an

	experimental testbed network covering much of the San Francisco Bay Area; and a local distribution network in the Boston Area, which is used for station software development." Kahn page 1494. "The user's terminal interface unit (TIU) also supports both formed of remote debugging. This feature has proven essential to the Bay Area PRNET development in that station software developers located in Boston and packet radio software developers in Texas can remotely participate in network debugging as the need arises, and new software versions can be conveniently installed from remote development sites as frequently as required." Kahn page 1494.
49. A system for managing an arrangement of application specific remote devices comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network

	can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute a multiplicity of computer programs, each computer program executed to generate at least one control signal in response to at least one application system input, said computer integrated with a wide area network (WAN);	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
at least one gateway connected to the WAN configured as a two-way communication device to receive and translate the at least one control signal and the at least one application system input; said gateway further configured to translate and transmit a radio-frequency (RF) signal containing the control signal and destination information, said gateway further configured to receive and translate the at least one application system input and source information;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

at least one wireless relatively low-power RF transceiver per computer program configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator and a sensor;	"In a packet-switched network, the unit of transmission is called a packet. It contains a number of data bits, and is usually of variable length up to a maximum of a few thousand bits. A packet includes all the addressing and control information necessary to correctly route it to its destination." Kahn page 1468. "We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481.

	"Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.

a sensor configured to translate a physical condition into an analog version of the application system input.	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses:

	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.

	‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16. ‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers.” ‘650 patent, 8:42-44. “For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112.” ‘650 patent, 10:54-57.

	'773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host

	protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. '817 patent, 6:1-8.
53. The system as defined in claim 49, wherein the	The above contentions for claim 49 are hereby incorporated by reference.

WAN is a dedicated Intranet.	"At the present time, two packet radio experimental networks are operating: an experimental testbed network covering much of the San Francisco Bay Area; and a local distribution network in the Boston Area, which is used for station software development." Kahn page 1494. "The user's terminal interface unit (TIU) also supports both formed of remote debugging. This feature has proven essential to the Bay Area PRNET development in that station software developers located in Boston and packet radio software developers in Texas can remotely participate in network debugging as the need arises, and new software versions can be conveniently installed from remote development sites as frequently as required." Kahn page 1494.
54. The system as defined in claim 49, wherein the at least one gateway is connected to the WAN by a network selected from the group consisting of a telecommunications network, private radio-frequency network, and a computer network.	The above contentions for claim 49 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
55. A method of collecting information and providing data services comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly

	into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481.

	"Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.

<tr>
<td>placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;</td>
<td>"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477.

"For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477.

For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the

	destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks.…" Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

60. A method for controlling an existing control system with a local controller comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
adaptively configuring a data translator disposed between and in communication with both a local controller and a wireless transceiver, wherein the data translator is configured to translate the local controller data stream into an information signal consisting of a transceiver identification code and a	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477.

concatenation of function codes, the data translator further configured to translate control signals from the wireless transceiver into local controller recognized control signals;	Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Kahn

	"Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.  **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.

remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495.

	"Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495.
processing the data into an RF signal;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a

	microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490.
transmitting the RF signal to a gateway;	"The functions of a station are associated with global management of the radio net [24]. Generally speaking, each station is aware of all operational radios in the network." Kahn page 1477. Figure 13, page 1489. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
translating the data in the RF signal into a network transfer protocol;	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by at least one sensor by generating an appropriate control signal;	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a

	cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
sending the control signal via the network to the gateway;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
translating the control signal from a network transfer protocol into an RF control signal;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
transmitting the RF control signal;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. 	the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
receiving the RF control signal;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
translating the received RF control signal into a local controller recognized control signal; and	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
applying the local controller recognized control signal via a local control to effect the desired system response.	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
61. The method of claim 60, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 60 are hereby incorporated by reference. "We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the

	system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital sections which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. Figure 6, Kahn page 1478. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to

	generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. Kahn page 1479

"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494.

"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.

62. The method of claim 60, wherein the network is the Internet.	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22

	"When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

	‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. '817 patent, 6:1-8.

Exhibit P1– Invalidity Chart for U.S. Patent No. 8,013,732 based on Kahn

The '732 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a use may select based on his application. The former category includes such capabilities as network transparency, area coverage/connectivity, mobile operation, internetting, coexistence, throughput with low delay, and rapid deployment. The last category includes error control options, routing options, and services for various tactical applications. … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. The Packet radio network merely provides a high throughput, low delay means of interconnection for the (potentially mobile) community of users." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated	"The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a

with a wide area network (WAN);	cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging." Kahn, p. 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22

	Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred

	across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.

	The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. This extends the range of the system beyond line of sight." Kahn, p. 1477. "For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to "double up" as a repeater, to support network traffic. In this case; we do not identify a separate backbone repeater network per se, since it would be indistinguishable from the network of user packet radios." Kahn, p. 1477. "Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, p. 1481. "The initial ARPA program objective was to develop a geographically distributed network consisting of an array of packet radios managed by one or more mini-computer based "stations," and to experimentally evaluate the performance of the system." Kahn, p. 1488.

	"Each radio has an identifier which we shall call its selector." Kahn, p. 1479. "For the purposes of this paper, we assume the selectors are unique for clarity in exposition." Kahn, p. 1479. "An important potential use of such a mechanism is to use the unique identifier of the next intended receiver as one input, thus generating a waveform which is associated with a particular slot and a particular receiver." Kahn, p. 1487 "While in the receive mode, each radio would use its own unique identifier to generate the reference pattern for its receiver." Kahn, p. 1487. Figure 13, page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes)." Kahn page 1490. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, p. 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, p. 1495. "At the conclusion of a measurement run, the data can be automatically spooled

Exhibit P1– Invalidity Chart for U.S. Patent No. 8,013,732 based on Kahn

	over the ARPANET to a remote site (e.g., UCLA) for analysis.” Kahn, p. 1495.  **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Kahn page 1479
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmit- ting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	“The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2] . The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET. The user's terminal interface unit (TIU) also supports both forms of remote debugging.” Kahn, p. 1494. “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the

	conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging

	functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile

device comprising:	subscribers to support computer communication and to provide local distribution of information of very a wide geographic area." Kahn page 1468. "A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs, or write and execute programs to run on remote hosts." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn, p. 1495.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users." Kahn page 1477. "Store-and-Forward Operation An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6)." Kahn page 1477.

Exhibit P1– Invalidity Chart for U.S. Patent No. 8,013,732 based on Kahn

	"Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn page 1477. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478.  **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Figure 8, Kahn page 1479. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures. … E. Point-to-Point Routing

	In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station sent the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet, and, at most, only a small finite set of them could be carried along." Kahn page 1479. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while and experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site. Operating software in the PRU's, TIU's and station performs collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station. From that station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.
the transceiver being further configured to wirelessly retransmit in the predetermined signal	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication

type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	network service to the users. These backbone radios, known as repeaters, receive packets from nearby users and relay them. The repeaters also accept packets from other nearby repeaters for relaying. … For military operation, where a separate backbone network might be infeasible to deploy, each user's radio might be equipped to support not only his own traffic but that of other designated users. That is, the user's radio may also have to double up" as a repeater, to support network traffic." Kahn page 1477. "Store-and-Forward Operation An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6)." Kahn page 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn page 1477. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures. … E. 	ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station sent the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet, and, at most, only a small finite set of them could be carried along." Kahn page 1479.
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. … For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. " Kahn page 1477.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and

	faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred

	embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless

	commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count,

	data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
17. The device of claim 13**,** wherein the data controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code	The above contentions for claim 13 are hereby incorporated by reference. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No.

	6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information of very a wide geographic area." Kahn page 1468. "A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs, or write and execute programs to run on remote hosts." Kahn page 1469.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"We assume that a set of radios distributed throughout a geographic area, which we call the backbone, provides a carrier-like packet communication network service to the users." Kahn page 1477. "Store-and-Forward Operation An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections are connected by a high speed interface (see Fig. 6)." Kahn page 1477. "Normal store-and-forward operation within the network takes place as

Exhibit P1– Invalidity Chart for U.S. Patent No. 8,013,732 based on Kahn

	follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn page 1477. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478.  **Fig. 8. Structure of a transmitted packet. (a) EPR packet format. (b) EPR packet preamble detail.** Figure 8, Kahn page 1479. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures. … E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it

	reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station sent the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header. However, this choice may have a significant impact on the network efficiency and ultimately its extendability since the selectors would contribute overhead to the packet, and, at most, only a small finite set of them could be carried along." Kahn page 1479. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while and experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site. Operating software in the PRU's, TIU's and station performs collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station. From that station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section

packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	contains a microprocessor controller plus semiconductor memory for packet buffering and software. … For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network. " Kahn page 1477.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). … We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs, or write and execute programs to run on remote hosts." Kahn page 1469. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. "From that station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when

	some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type

Exhibit P1– Invalidity Chart for U.S. Patent No. 8,013,732 based on Kahn

	Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31**,** further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more	The above contentions for claim 31 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross internetwork debugger known as X-NET. By using internet protocols to access

retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the

	destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16. ‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn page 1494. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No.

	6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn page 1494. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and

	faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control

	process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user

	application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the ARPANET." Kahn page 1494. "*1) Network Management and Control:* A centralized network management facility (NMF) has been developed for managing and operating the Bay Area testbed. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. *2) Debugging the Network:* All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 8,754,780 based on Kahn

The '780 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. In a system comprising a plurality of wireless devices, a device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information over a wide geographic area." Kahn Abstract.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477.

	"Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479 Figure 9, Kahn page 1480 Figure 12, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490. "In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn page 1479.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. … The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. … For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate,

	power, and time of transmission. In addition, it performs the packet processing to route the packet through the network." Kahn page 1477. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490. "One of the requirements for controlling the PRNET is assessing the reliability of radio links between PR's and using the information to assign good routes. A primary source of link information is the PR neighbor table whose entries are collected by each radio, summarized, and regularly sent to the station along with other status information." Kahn page 1477. "3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP's (terminal-on packets), which serve much the same function as their counterpart summary ROP's. Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on information contained in the ROP's for assigning routes. Kahn page 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted,

	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495. "2) PRU measurement software-collects subnet CUMSTATS and snapshots; enters local data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms." Kahn page 1495.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the

	command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that

	causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data

	bases, manipulate files, run programs or write and execute programs to run on remote hosts. … Many of these operations will be interactive, with a computer response to a remote user entry being desired in real time." Kahn page 1469. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute

	jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its

	most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. … The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. … For each transmitted packet, the digital unit selects the transmit frequency (normally fixed), data rate, power, and time of transmission. In addition, it performs the packet processing to route the packet through the network." Kahn page 1477. "Each EPR consists of a radio unit, which transmits and receives

	packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490. "Each radio has an identifier which we shall call its selector. The selectors play a central rile in the network routing and control procedures." Kahn page 1479 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging."

	Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be

	programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been

	obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and

	depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command

	or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. Figure 9 Kahn page 1480. "The location of the major elements of the packet radio tested during 1977 is shown in Fig. 12." Kahn page 1488. Figure 12, Kahn page 1489.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 8.908,842 based on Kahn

The '842 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. A device for communicating information, the device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio." Kahn Abstract.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a user may select based on his application." Kahn page 1469. "We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. … Many of these operations will be interactive, with a computer response to a remote user entry being desired in real time." Kahn page 1469. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490.

	"The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13, Kahn page 1489.
an interface circuit for communicating with a central location; and	"The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13, Kahn page 1489 (e.g., "TERMINAL/STATION INTERFACE" "The interface between the user equipment and the EPR digital unit is the portal through which packets enter and leave the network." Kahn page 1490. "The functions of a station are associated with global management of the radio net [24]. Generally speaking, each station is aware of all operational radios in the network." Kahn page 1477.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"Each radio has an identifier which we shall call its selector." Kahn page 1479. "The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13. (discloses a "microprocessor" coupled to the "terminal/Station interface" and the "radio unit" transceiver.

	Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490. "When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access (DMA) control. The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and adds (modulo two) the appropriate PN chip pattern for the selected data rate. .. When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions. …The microprocessor executes the appropriate protocol software to determine whether the received packet should be relayed, delivered to an attached user, or station, or discarded." Kahn page 1490.
7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The above contentions for claim 1 are hereby incorporated by reference. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures." Kahn page 1479.

	"In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header." Kahn page 1479.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The above contentions for claim 1 are hereby incorporated by reference. "In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header." Kahn page 1479.
16. A device for communicating information, the device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio." Kahn Abstract.
a processor; and	"The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13…." Fig. 13 discloses a "microprocessor" coupled to the "terminal/Station interface" and the "radio unit" transceiver. Kahn page 1489.
a memory, the memory comprising logical instructions that when executed by the processor are configured to cause the device to:	"When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access (DMA) control." Kahn page 1490.
wirelessly transmit a signal comprising instruction data for	"Each EPR consists of a radio unit, which transmits and receives

delivery to a network of addressable low-power transceivers;	packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490. "The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and add (modulo two) the appropriate PN chip pattern for the selected data rate. The resulting PN modulated stream is then applied to a minimum shift keying (MSK) modulator, and the signal is up-converted to a selected 20MHz portion of the 1710-1850 MHz band, power amplified, and transmitted through an azimuthally omnidirectional antennae." Kahn p. 1490.
establish a communication link between at least one low-power transceiver in the network of addressable low-power transceivers and a central location based on an address included in the signal, the communication link comprising one or more low-power transceivers in the network of addressable low-power transceivers; and	"The packet preamble is used by the radio section of the receiver for several purposes. The first few bits are used to detect the carrier energy and to set the automatic gain control (AGC) to compensate for different signal strengths of the arriving packets. Correct reception of the packet is totally dependent upon acquisition of the preamble. The next few bits are used to acquire bit timing. Following these, the next set of bits is used to acquire packet timing (identify the end of the preamble and the start of the header). Both the header and text are delivered from the radio section to the digital section which knows the header format and can therefore determine the exact start of the text." Kahn page 1478-79. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control

	procedures." Kahn page 1479. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn page 1479. "Protocols currently implemented are the channel access protocol (CAP), the reliable station to PR protocol (SPP), a statistics gathering feature called CUMSTATS, and a debugging package called X-RAY. CAP is responsible for the primary EPR function of transferring packets to or from the adjacent EPR on a route through the network. CAP is responsible for monitoring the hop-by-hop echo acknowledgment process, retransmission of nonacknowledged packets, invoking alternate routing procedures, and determining packet disposition." Kahn page 1490.
receive one or more low-power RF signals and communicate information contained within the signals to the central location	"In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one

along with a unique transceiver identification number over the communication link.	or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn page 1479. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn page 1490.
17. A device for communicating information, the device comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio." Kahn Abstract.
a low-power transceiver that is configured to wirelessly receive a signal including an instruction data from a remote device;	"A primary objective of a packet radio network is to support real-time interactive communications between computer resources (hosts) connected to the network and user terminals (e.g., terminal-host, host-host, and terminal-terminal interactions). In

	order to satisfy this objective, the network should provide certain basic capabilities and services which can be grouped roughly into two categories: those which are always or automatically provided by the network and those which a user may select based on his application." Kahn page 1469. "We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts. … Many of these operations will be interactive, with a computer response to a remote user entry being desired in real time." Kahn page 1469. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490. "The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13, Kahn page 1489.
an interface circuit for communicating with a central location;	"The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13, Kahn page 1489 (e.g., "TERMINAL/STATION

Exhibit P1 – Invalidity Chart for U.S. Patent No. 8.908,842 based on Kahn

	INTERFACE" "The interface between the user equipment and the EPR digital unit is the portal through which packets enter and leave the network." Kahn page 1490. "The functions of a station are associated with global management of the radio net [24]. Generally speaking, each station is aware of all operational radios in the network." Kahn page 1477.
a controller coupled to the interface circuit and to the low-power transceiver, the controller being configured to establish a communication link between the remote device and the central location using address-indicative data included in the signal;	"Each radio has an identifier which we shall call its selector." Kahn page 1479. "The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13. (discloses a "microprocessor" coupled to the "terminal/Station interface" and the "radio unit" transceiver. Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490. "When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access

	(DMA) control. The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and adds (modulo two) the appropriate PN chip pattern for the selected data rate. .. When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions. …The microprocessor executes the appropriate protocol software to determine whether the received packet should be relayed, delivered to an attached user, or station, or discarded." Kahn page 1490.
the controller further configured to receive one or more data signals from the central location via the interface circuit and communicate information contained within the signals to the remote device.	"Each radio has an identifier which we shall call its selector." Kahn page 1479. "The EPR design which has been implemented for use in the testbed is functionally described as in Fig. 13 (also see Fig. 6)." Kahn page 1489. Figure 13. (discloses a "microprocessor" coupled to the "terminal/Station interface" and the "radio unit" transceiver. Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490.

Kahn page 1490. "The microprocessor executes the appropriate protocol software to determine whether the received packet should be relayed, delivered to an attached user or station, or discarded." Kahn page 1490. "SPP is an end-to-end protocol which is used for reliable delivery of network monitor and control packets, such as labelling packets sent to an EPR." Kahn page 1490.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

The '893 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481 "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, page 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, page 1495. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481 "Each radio has an identifier which we shall call its selector." Kahn, page 1479. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, page 1477. "Each packet is uniquely identified by a set of bits in its header called the Unique Packet Identification (UPI)." Kahn page 1477. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48-bit preamble followed by a variable length header (typically 96-144 bits) followed by the text and a 32-bit checksum." Kahn, page 1478. Figure 8 Kahn page 1479. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is

	first determined by a station, which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, page 1479 "Within the PRNET, stations and radios need to communicate control packets reliably. … The Station-PR Protocol (SPP) provides the reliable delivery system." Kahn, page 1481.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, page 1477.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48-bit preamble

	followed by a variable length header (typically 96-144 bits) followed by the text and a 32-bit checksum." Kahn, page 1478. Figure 8. Kahn page 1479.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …

	Routing Header: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network

	service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that

	uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, page 1479.
a command indicator comprising a command code;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional

	references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

at least one data value comprising a scalable message; and	"When a packet is to be transmitted, the processor activates a DMA channel to control and monitor the transmission. Under DMA control, the packet is read from the processor memory, convolutionally encoded with a constraint length 24 code, and loaded into a buffer prior to scrambling (bit order permutation). The packet data is read from the buffer bit by bit in pseudorandom order, differentially encoded, and passed to the spread spectrum modulator where each data bit is modulo two added to each chip of the PN chip sequence used to encode that bit. The PN modulated chip sequence is then passed to an MSK modulator, implemented with a SAW device, and having an IF output at 300 MHz. This signal is up-converted to 1780 MHz, amplified to l O W, and fed to the azimuthally omnidirectional antenna. Fig. 15 shows the basic UPR packet and preamble format. In the discussion above, only the header and text bits of the packet are read from the processor memory. The preamble and postamble bits are supplied by the code generator circuitry, and are used in combination by the receiver to determine the receive data rate and coding format of the packet." Kahn, p. 1491. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers,

	which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector;	"The EPR radio unit operates with a fixed PN spread spectrum

and	pattern which, for simplicity in implementation, is identical for each transmitted bit. Two transmission data rates are available, 100 and 400 kbits/s, with corresponding spread spectrum patterns of 128 and 32 chips per bit, respectively. The 100-kbits/s rate is used for links with potentially large multipath spreads because the fixed bit length PN chip pattern does not provide the ability to discriminate against intersymbol interference. The radio unit operates in a half duplex mode. When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access (DMA) control. The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and adds (modulo two) the appropriate PN chip pattern for the selected data rate. The resulting PN modulated stream is then applied to a minimum shift keying (MSK) modulator, and the signal is up-converted to a selected 20 MHz portion of the 1710-1850 MHz band, power amplified, and transmitted through an azimuthally omnidirectional antenna." Kahn, p. 1490.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages.	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, p. 1495.
2. The system of claim 1, wherein the plurality of transceivers further comprise at least one integrated transceiver, wherein the integrated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers; and	"1) Network Monitoring and Control: A centralized network management facility (NMF) has been developed for managing

	and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. … 3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP (terminal-on packets) , which serve much of the same function as their counterpart summary ROP's." Kahn page 1494.
a sensor detecting a condition and outputting a sensed data signal to the transceiver.	"1) Network Monitoring and Control: A centralized network management facility (NMF) has been developed for managing and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. … 3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically

	send summary TOP (terminal-on packets) , which serve much of the same function as their counterpart summary ROP's." Kahn page 1494.
3. The system of claim 2, wherein the at least one integrated transceiver receives the preformatted command message requesting sensed data, confirms the receiver address as its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet, wherein the packets are equal to the number of segments.	The above contentions for claim 2 are hereby incorporated by reference. "We assume that computer resources (hosts) need to be connected with each other and with individual users who might access data bases, manipulate files, run programs or write and execute programs to run on remote hosts….Many of these operations will be interactive, with a computer response to a remote user entry being desired in real-time." Kahn page 1469. "1) Network Monitoring and Control: A centralized network management facility (NMF) has been developed for managing and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated. … 3) System Monitoring: Once initialized, each packet radio in the network periodically announces its existence by transmitting to the station summary ROP's which contain neighbor tables and other status information. Similarly, terminal devices periodically send summary TOP (terminal-on packets) , which serve much of the same function as their counterpart summary ROP's." Kahn

	page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed

	throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to

	eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and

	"network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers;	"2) Debugging the Network: All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the

	ARPANET to a remote site (e.g., UCLA) for analysis." Kahn page 1495.
a sensor detecting a second condition and outputting a sensed data signal to the transceiver; and	"2) Debugging the Network: All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. 	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated. At the conclusion of a measurement run, the data can be automatically spooled over the ARPANET to a remote site (e.g., UCLA) for analysis." Kahn page 1495.
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481 "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, page 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, page 1495.
a plurality of transceivers, each transceiver being in	"Consider a collection of geographically distributed packet radios,

communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481 "Each radio has an identifier which we shall call its selector." Kahn, page 1479. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, page 1477. "Each packet is uniquely identified by a set of bits in its header called the Unique Packet Identification (UPI)." Kahn page 1477. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48-bit preamble followed by a variable length header (typically 96-144 bits) followed by the text and a 32-bit checksum." Kahn, p. 1478. Figure 8, Kahn page 1479. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station, which is the only element in the net

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, p. 1479 "Within the PRNET, stations and radios need to communicate control packets reliably. … The Station-PR Protocol (SPP) provides the reliable delivery system." Kahn, p. 1481.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, page 1477.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, page 1479.

sender address comprising the unique address of the sending transceiver;	"In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, page 1479.
a command indicator comprising a command code;	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute

	jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its

	most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"When a packet is to be transmitted, the processor activates a DMA channel to control and monitor the transmission. Under DMA control, the packet is read from the processor memory, convolutionally encoded with a constraint length 24 code, and loaded into a buffer prior to scrambling (bit order permutation). The packet data is read from the buffer bit by bit in pseudorandom order, differentially encoded, and passed to the spread spectrum modulator where each data bit is modulo two added to each chip of the PN chip sequence used to encode that bit. The PN modulated chip sequence is then passed to an MSK modulator, implemented with a SAW device, and having an IF output at 300 MHz. This signal is up-converted to 1780 MHz, amplified to l O W, and fed to the azimuthally omnidirectional antenna. Fig. 15 shows the basic UPR packet and preamble format. In the discussion above, only the header and text bits of

	the packet are read from the processor memory. The preamble and postamble bits are supplied by the code generator circuitry, and are used in combination by the receiver to determine the receive data rate and coding format of the packet." Kahn, p. 1491. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields).

	"The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class

	address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message

	format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector;	"The EPR radio unit operates with a fixed PN spread spectrum pattern which, for simplicity in implementation, is identical for each transmitted bit. Two transmission data rates are available, I 00 and 400 kbits/s, with corresponding spread spectrum patterns of 128 and 3 2 chips per bit, respectively. The I 00-kbits/s rate is used for links with potentially large multipath spreads because the fixed bit length PN chip pattern does not provide the ability to discriminate against intersymbol interference. The radio unit operates in a half duplex mode. When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access (DMA) control. The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and adds (modulo two) the appropriate PN chip pattern for the selected data rate. The resulting PN modulated stream is then applied to a minimum shift

	keying (MSK) modulator, and the signal is up-converted to a selected 20 MHz portion of the 1710-1850 MHz band, power amplified, and transmitted through an azimuthally omnidirectional antenna." Kahn, p. 1490.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages; and	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, p. 1490. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, p. 1477. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, p. 1495.
wherein at least one of the plurality of transceivers further sends preformatted emergency messages.	"Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the

	independent network monitoring system also listens to ROP's and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module,

	or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
18. The system of claim 17, wherein the controller maintains periods of silence by not sending the preformatted command messages during predetermined time periods; and	The above contentions for claim 17 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
wherein the at least one of the plurality of transceivers detects a period of silence and sends the preformatted emergency message during the period of silence.	"Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged. When active, the independent network monitoring system also listens to ROP's and maintains a table of the last time that ROP's and TOP's were heard, for each packet radio or terminal interface unit ID. Thus, the exact time of failure of any network element can be obtained-even if a component of the station fails." Kahn page 1494. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it

	is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
37. A method of communicating between geographically remote devices, the method comprising:	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. "Measurement facilities have been built into the PR and station software. They provide for the collection and delivery of measurement data over the radio channel in real-time while an experiment is being run; after the experiment has been completed, the data are reduced and analyzed at a remote site." Kahn, page 1495. "Operating software in the PRU's, TIU's, and station performs the collection of measurement data and uses the system protocols for delivery of this data to a measurement file located at the station." Kahn, page 1495.
sending a message;	"Consider a collection of geographically distributed packet radios, each of which is powered on and capable of communicating packets to some subset of radios within line of sight propagation range." Kahn, page 1481 "Each radio has an identifier which we shall call its selector." Kahn, page 1479. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio

	section for transmission to a nearby repeater which is identified within the packet." Kahn, page 1477.
receiving the message at one or more of the remote devices;	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490. "When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions." Kahn page 1490.
processing the message;	"When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions." Kahn page 1490.
preparing a response message;	"Many of these operations will be interactive, with a computer response to a remote user entry being desired in real-time." Kahn page 1469. "From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated." Kahn page 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off,

	and data collection may be initiated." Kahn, page 1495. "Both the station and the network monitor make extensive use of summary ROP's and TOP's. The station maintains a connectivity matrix based on the information contained in the ROP's for assigning routes. Current network connectivity may be displayed at the station upon request, and all state changes for nodes and links may be time stamped and logged." Kahn page 1494.
receiving the response message;	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490. "When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions." Kahn page 1490.
processing the response message	"When not transmitting, the EPR remains in the receive mode. An arriving packet proceeds through RF amplification, down-conversion, IF amplifier and wide-band (noncoherent) automatic gain control (AGC) functions." Kahn page 1490.
wherein all messages comprise at least one packet, the packet having a predetermined format;	"Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of the packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet." Kahn, p. 1477.

	"Each packet is uniquely identified by a set of bits in its header called the Unique Packet Identification (UPI)." Kahn p. 1477. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48-bit preamble followed by a variable length header (typically 96-144 bits) followed by the text and a 32-bit checksum." Kahn, p. 1478. "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station, which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and or destination identifier but would not have to carry the entire route in its header." Kahn, p. 1479 "Within the PRNET, stations and radios need to communicate control packets reliably. … The Station-PR Protocol (SPP) provides the reliable delivery system." Kahn, p. 1481.
wherein the predetermined format comprises:	
a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	"Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures. We discuss the point-to-point and broadcast routing

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	option below. … E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header." Kahn page 1479.
a sender address comprising an unique address of the sender;	"Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures. We discuss the point-to-point and broadcast routing option below. … E. Point-to-Point Routing In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination

	identifier but would not have to carry the entire route in its header." Kahn page 1479.
a command indicator comprising a command code;	"From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected, diagnosed, and isolated." Kahn page 1494. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the

	monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses:

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than

	they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are

	desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type

	ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector that is a redundancy check error detector; and	"For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits)

Exhibit P1 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Kahn

	followed by the text and a 32 bit checksum." Kahn page 1478. Figure 8, Kahn page 1479. "We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking." Kahn page 1481. "When a packet is transmitted, the preamble, header and text are read from microprocessor memory under direct memory access (DMA) control. The radio unit completes the packet format previously illustrated in Fig. 8 by adding a 32 bit cyclic redundancy checksum (CRC), then differentially encodes the data, and adds (modulo two) the appropriate PN chip pattern for the selected data rate." Kahn page 1490.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"We assume an end-to-end error detection and retransmission technique to be used in the network for reliable delivery of individual packets. Each source/destination pair on the network could utilize an end-to-end protocol such as described in [38], which also supports internetworking." Kahn page 1481.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Jubin

The '492 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.
a receiver address comprising a scalable address of at least one remote device;	"*A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a command indicator comprising command code;	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet

	network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	*"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.

	ETE Header: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a controller associated with a remote device comprising a transceiver configured to send and receive wireless signals, the remote device configured to send a preformatted message comprising the receiver address, a command indicator, and the data value via the transceiver to at least one other remote device.	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via a HDLC wire interface." Jubin page 22. "The LPR consists of both digital and RF subsystems. … The

	digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 "Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. "D. Receive Measurements Several measurements on the receive side are provided to the software: receive power (AGC), signal + noise, noise, multipath,

	and FEC error count.. These can be used to better quantify the link qualities between neighboring PRs (Section III-A) that provide the basis for the PRNET routing algorithms (Section III-B)." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed

	through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by reference.
a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin page 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via a HDLC wire interface." Jubin page 22. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22.

	"*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	"The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition

	to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. 6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from at least one other transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.

providing a receiver to receive at least one message;	"The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22.
wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via an HDLC wire interface." Jubin page 22. "Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "C. *Error control* *Forward Error Correction:* The LPR uses long convolutional codes and sequential decoding to perform forward error correction (FEC). … The LPR also has hardware to generate a

	32-bit cyclic redundancy checksum (CRC)." Jubin page 27. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central

	station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer

	operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the

	system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to

	individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message

	includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	*"Forwarding:* Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's headers and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26. "Other PRs within range also receive each transmitted packet. For example, L's transmission is received not only by M but also by P and Q. Since neither P nor Q is the next PR in the routing header, they both discard the packet." Jubin page 26.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio	The above contentions for claim 8 are hereby incorporated by reference. "The PRNET provides, via a common radio channel, the

frequency transmissions.	exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network

	service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP

	addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contentions for claim 8 are hereby incorporated by reference. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 "*Adaptive Power Control*: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contentions for claim 8 are hereby incorporated by reference. "C. *Error control* *Forward Error Correction:* The LPR uses long convolutional codes and sequential decoding to perform forward error correction (FEC). … The LPR also has hardware to generate a 32-bit cyclic redundancy checksum (CRC)." Jubin page 27.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.
a transceiver configured to send and receive wireless communications; and	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically

	separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin page 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via a HDLC wire interface." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are

	available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 "Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once

	every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet."

	'252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing

15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "Another host computer function called Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. "D. Receive Measurements Several measurements on the receive side are provided to the software: receive power (AGC), signal + noise, noise, multipath, and FEC error count.. These can be used to better quantify the link qualities between neighboring PRs (Section III-A) that provide the basis for the PRNET routing algorithms (Section III-B)." Jubin page 31.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. *"Forwarding:* Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's headers and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26.

	"Other PRs within range also receive each transmitted packet. For example, L's transmission is received not only by M but also by P and Q. Since neither P nor Q is the next PR in the routing header, they both discard the packet." Jubin page 26.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contentions for claim 14 are hereby incorporated by reference. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 "*Adaptive Power Control*: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No.

	5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message

	with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference.

	"*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. Figure 6, Jubin page 25.

	"Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via a HDLC wire interface." Jubin page 22. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and	"Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. *"ETE Header*: The ETE header is created by the source device.

an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "C. *Error control* *Forward Error Correction:* The LPR uses long convolutional codes and sequential decoding to perform forward error correction (FEC). … The LPR also has hardware to generate a 32-bit cyclic redundancy checksum (CRC)." Jubin page 27. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet

	network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link

	packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for

	each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43

	illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "Another host computer function called Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. "D. Receive Measurements Several measurements on the receive side are provided to the software: receive power (AGC), signal + noise, noise, multipath, and FEC error count.. These can be used to better quantify the link qualities between neighboring PRs (Section III-A) that provide the basis for the PRNET routing algorithms (Section III-B)." Jubin page 31.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page

	22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important advantages to the user of the network." Jubin page 21.
a transceiver configured to send and receive wireless communications; and	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated. As a communication medium, broadcast radio (as opposed to wires and antenna-directed radio) provides important

	advantages to the user of the network." Jubin page 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin page 22. "In order for a user to send data across a PRNET, a device (such as a small host computer) must be connected to a packet radio via a HDLC wire interface." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. …Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. Figures 2 and 6, Jubin pages 22, 25.

a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	"The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 "Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25. "*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. "IV. Forwarding Protocols

	Despite the local broadcast nature of the packet radio, a user packet is not flooded throughout the PRNET to get to its destination because multiple-hop flooding would use too much of the finite capacity of the network's common channel. Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B). … Forwarding is accomplished via information read from the device and tier tables (Sections III-B and III-C) and from the packet headers (Section IV-A). Forward error correction increases the probability of error-free reception and cyclic redundancy checksums prevent, with high probability, the forwarding of packets that are not error-free (Section IV-C)." Jubin page 25. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected

	devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its

	most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,468,661 based on Jubin

The '661 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a computer configured to execute at least one computer program	Figure 4, Jubin page 23.

that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22.

	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an

transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
5. A system for monitoring remote devices, comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality,

	nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,468,661 based on Jubin

	attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. Figs. 2 and 6.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23.

	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
9. A system for controlling a remote device comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to

	organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
a target remote device having an actuator to be controlled;	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "All commands available to a local operator are available to a remote operator. The remote operator can load/debug not only a PR that is executing the regular protocol software, but also a 'frozen' PR, that is, a PR that has stopped executing the regular program because of a self-detected fault." Jubin page 23. "Adaptive Power Control: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31.

a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,468,661 based on Jubin

	modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a gateway connected to the WAN configured to receive and	"The PRNET can also be accessed from other networks via an

translate the at least one control signal	Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. Figs. 2 and 6. "Adaptive Power Control: The hardware provides the software

	the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"Adaptive Power Control: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted,

	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS

	message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication

	network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Adaptive Power Control: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22.

	"Adaptive Power Control: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31.
12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor

	will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	Figure 4, Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... Jubin page 25. *"ETE Header*: The ETE header is created by the source device.

	It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 12 are hereby incorporated by reference. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA

	Internet." Jubin, p. 22

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Jubin

The '692 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. A system for remote data collection, assembly, and storage comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	Figure 4, Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and

	debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at	"The PRNET system comprises:

defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	• The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR

	correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22.
4. The system as defined in claim 1, wherein each	The above contentions for claim 1 are hereby incorporated by reference.

wireless transmitter is integrated with a sensor.	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding network behavior." Jubin page 23.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B_. Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by

	every intermediate packet radio." Jubin pages 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer

	or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "A host computer may be directly interfaced to a PR. If a user wished to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU)[8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22. Figure 4, Jubin page 23.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Jubin

8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "A host computer may be directly interfaced to a PR. If a user wished to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU)[8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.

12. The system as defined in claim 1, wherein the gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	The above contentions for claim 1 are hereby incorporated by reference. "A. Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard

	internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page

	22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP)

	signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.

	The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
14. The system as defined in claim 1, wherein the WAN is a dedicated Intranet.	The above contentions for claim 1 are hereby incorporated by reference. "Note that, organizationally, the devices lie outside the PRNET subnet: the network appears as a black box providing packet communication service between pairs of user devices. Jubin page 23. Fig. 4, Jubin page 23.
24. A method for controlling a system comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21.
remotely collecting data from at least one sensor;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting the community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin page 22.

	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
processing the data into a radio-frequency (RF) signal;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
transmitting the RF signal, via a relatively low-	"Each PR is responsible for receiving a packet and relaying it on to a PR that is

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Jubin

power transceiver, to a gateway;	one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22.
translating the data in the RF signal into a network transfer protocol;	"A host computer may be directly interfaced to a PR. If a user wished to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU)[8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22. Figure 4, Jubin page 23.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by the at least one sensor by generating an appropriate control signal;	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator. The remote operator can load/debug not only a PR that is executing the regular protocol software, but also a "frozen" PR, that is, a PR that has stopped executing the regular program because of a elf-detected fault." Jubin page 23.
sending the control signal via the network to the gateway,	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.
translating the control signal from a network transfer protocol into an RF control signal;	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22.

	Figs. 2 and 6. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator. The remote operator can load/debug not only a PR that is executing the regular protocol software, but also a "frozen" PR, that is, a PR that has stopped executing the regular program because of a self-detected fault." Jubin page 23 "Single-hop radio networks are also being used to improve the efficiency of commercial operations. For example, the use of a small hand-held radio with a limited keyboard is being experimented with by restaurants. The waiters, bartenders, and cooks are all equipped with a packet radio. The waiter enters and order and its destination (either the bartender or the cook), then waits to receive a packet indicating that the order has been completed." Jubin page 32.
transmitting the RF control signal;	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
receiving the RF control signal;	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF

	subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
translating the received RF control signal into an analog signal; and	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22.

	Figs. 2 and 6.
applying the analog signal to an actuator to effect the desired system response.	*"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
25. The method of claim 24, wherein the RF signal contains a concatenation of information comprising encoded data information and transmitter identification information from an originating transmitter.	The above contentions for claim 24 are hereby incorporated by reference. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its

	forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
26. The method of claim 25, wherein the step of transmitting the RF signal is further performed by at least one transceiver, wherein the transceiver is configured to concatenate a transceiver identification code to the RF signal.	The above contentions for claim 25 are hereby incorporated by reference. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.

	"*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26.
27. The method of claim 25, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 25 are hereby incorporated by reference. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22.

	"The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "A. Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by

	every intermediate packet radio." Jubin pages 25-26. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator. The remote operator can load/debug not only a PR that is executing the regular protocol software, but also a "frozen" PR, that is, a PR that has stopped executing the regular program because of a elf-detected fault." Jubin page 23
28. The method of claim 25, wherein the steps of translating and applying the received RF control signal are performed only by an identified transceiver electrically integrated with an actuator.	The above contentions for claim 25 are hereby incorporated by reference. *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 25 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. "A host computer may be directly interfaced to a PR. If a user wished to send

	data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU)[8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16.

	'650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses:

	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
30. The method of claim 25, wherein the network is an Intranet.	The above contentions for claim 25 are hereby incorporated by reference. "Note that, organizationally, the devices lie outside the PRNET subnet: the network appears as a black box providing packet communication service between pairs of user devices. Jubin page 23. Fig. 4, Jubin page 23.
31. The method of claim 25, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 25 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example:

	Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol

	congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP

	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
32. A system for monitoring remote devices comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"PRs can be loaded and debugged from a remote host computer. All commands available to a local operation are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available to for local debugging." Jubin page 23. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a low-power radio-frequency (RF) signal;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users.

	• The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. "A. Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR

	correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). Also in the ETE header is a type-of –service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26.
at least one gateway connected a wide area network (WAN) configured to receive and translate the RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for	Figure 4, Jubin page 23. "A plethora of terminal commands – display memory, alter memory,

retrieval upon demand from a remotely located device.	select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22.
36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	The above contentions for claim 32 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22.

	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from

	the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." 42. A system for controlling remote devices comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21.
a computer configured to execute at least one	Figure 4, Jubin page 23.

computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs

	while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22.

	"The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"PRs can be loaded and debugged from a remote host computer. All commands available to a local operation are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available to for local debugging." Jubin page 23. *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-

	far" problem." Jubin page 31.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"A. Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. ETE Header: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B_. Also in the ETE header is a type-of – service flag that the source PR transfers to the routing header to customize forwarding for low delay/reliability applications such as speech (Section V-D). The ETE headers stays on the packet from its creation by the source device throughout its forwarding through the PRNET including its delivery to the destination device. Routing Header: The routing header is created by the source PR, encapsulating the ETE header. … The routing header stays on the packet throughout its forwarding throughout the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR, The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of

	one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is

	accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the

	destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16. ‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26.

	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between

	hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Note that, organizationally, the devices lie outside the PRNET subnet: the network appears as a black box providing packet communication service between pairs of user devices. Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. 	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
49. A system for managing an arrangement of application specific remote devices comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a computer configured to execute a multiplicity of computer programs, each computer program executed to generate at least one control signal in response to at least one application system input, said computer integrated with a wide area network (WAN);	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet

	radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
at least one gateway connected to the WAN configured as a two-way communication device to receive and translate the at least one control signal and the at least one application system input; said gateway further configured to translate and transmit a radio-frequency (RF) signal containing the control signal and destination information, said gateway further configured to receive and translate the at least one application system input and source information;	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
at least one wireless relatively low-power RF transceiver per computer program configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached

transceiver electrically coupled with an actuator and a sensor;	to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response; and	"PRs can be loaded and debugged from a remote host computer. All commands available to a local operation are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available to for local debugging." Jubin page 23. *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
a sensor configured to translate a physical condition into an analog version of the application system	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers

input.	measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station

	processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. …

	2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16. ‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors

	110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Jubin

52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

signal consisting of a transmitter code and an information field;	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable an d robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "Note that, organizationally, the devices lie outside the PRNET subnet: the network appears as a black box providing packet communication service between pairs of user devices. Jubin page 23.
adaptively configuring at least one transmitter with the data translator, wherein the transmitter converts the information signal into a low-power RF signal;	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET

received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;	subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Jubin

	used in forwarding (Section IV-B)." Jubin page 25.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable an d robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.

granting client access to the computer.	"Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22.
56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 49 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet

	System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet

	gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
59. The method of claim 55 wherein the clients access the information using a web browser.	The above contentions for claim 49 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page

applying the local controller recognized control signal via a local control to effect the desired system response.	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 *"Adaptive Power Control:* The hardware provides the software the capability to select, on a packet-by-packet basis, the attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
61. The method of claim 60, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22.

	"The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.
62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example:

	Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol

	congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.” ‘217 patent, 46:11-16. ‘650 patent discloses “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112.

	However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP

	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.
64. The method of claim 60, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 60 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22.

	Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. '817 patent, 6:1-8.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Jubin

The '732 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated	The above contentions for claim 25 are hereby incorporated by reference. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

with a wide area network (WAN);	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22. "A host computer may be directly interfaced to a PR. If a user wished to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU)[8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from

	the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is

	the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	The above contentions for claim 25 are hereby incorporated by reference. "Note that, organizationally, the devices lie outside the PRNET subnet: the network appears as a black box providing packet communication service between pairs of user devices. Jubin page 23. Fig. 4, Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494.

	Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located

	anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and

	debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23. "Another application of packet radio networks currently being explored in the requirement for providing distributed access to either distributed or centralized information." Jubin page 31.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer

	or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"A Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25. "*Forwarding*: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26.

the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"*Forwarding*: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26.
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets over the radio channel. .. Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6.

	"Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. "*Forwarding*: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between

	hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22 "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*Adaptive Power Control:* The hardware provides the software with the capability to select, on a packet by packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9

	during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. Figure 4, Jubin page 23. "The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22 "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure,

	etc.—are available for local debugging." Jubin page 23. "*Adaptive Power Control:* The hardware provides the software with the capability to select, on a packet by packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page

	247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and

	that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

17. The device of claim 13**,** wherein the data controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code	The above contentions for claim 13 are hereby incorporated by reference. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"A Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is

	used in forwarding (Section IV-B). …*Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25. "*Forwarding*: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred

	embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

18. The device of claim 13, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the data controller can implement.	"The protocol software and replacement ("patches") to operating-system firmware in the PR can be loaded into the PR from a terminal via an RS-232 interface. A plethora of terminal commands- display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging. …PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "After a PR (say PR *L* in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity. Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions,

	commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the command.	The above contentions for claim 13 are hereby incorporated by reference. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*Adaptive Power Control:* The hardware provides the software with the capability to select, on a packet by packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command

	the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Jubin

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"In this paper we describe the current state of the DARPA packet radio network. Fully automated algorithms and protocols to organize, control, maintain, and move traffic through the packet radio network have been designed, implemented, and tested." Jubin page 21. "The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, p. 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF

	subsystems." Jubin, p. 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"A Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25. "*Forwarding*: Packets are forwarded over a single path through the PRNET by

	each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics.. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The LPR consists of both digital and RF subsystems. … The digital subsystem controls the routing and flow of packets over the radio channel. .. Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that

	is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. "*Forwarding*: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's header and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

	"*Adaptive Power Control*: The hardware provides the software with the capability to select, on a packet by packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data

	acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31, further comprising at least one gateway connected	The above contentions for claim 31 are hereby incorporated by reference.

to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin p. 23. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, p. 22 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example: Kahn discloses: "The PRNET is normally connected to the ARPANET. This connection is accomplished using a gateway [34] process, co-located with the network station processor, to communicate with an ARPANET IMP [2]. The station can then be remotely debugged from an authorized ARPANET host using a cross-internetwork debugger known as X-NET. By using internet protocols to access the station's X-RAY process, even the radios can be remotely debugged from the Arpanet." Kahn page 1494. Burchfiel discloses: "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and

	TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. '217 patent discloses: "The data collection module will send and receiving information to and from

	the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands—display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*Adaptive Power Control*: The hardware provides the software with the capability to select, on a packet by packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control

	Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "The protocol software and replacement ("patches") to operating-system firmware in the PR can be loaded into the PR from a terminal via an RS-232 interface. A plethora of terminal commands- display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging. …PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"After a PR (say PR *L* in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when

	some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. Exhibit P2 – Invalidity Chart for U.S. Patent No. 8,754,780 based on Jubin

The '780 Patent – Claim	**J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.**
1. In a system comprising a plurality of wireless devices, a device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, page 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22.

	Figs. 2 and 6. Jubin pages 22 and 25. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. *"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. *"A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … The packet

	headers that are of concern to this paper are the end-to-end header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25 (see also Table of routing header fields). "The routing header stays on the packet throughout its forwarding through the PRET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin pages 25-26.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. "Another host computer function called the Network Monitor is

	used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid network designers in characterizing and understanding the network behavior." Jubin page 23.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is

	preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. *"A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … The packet headers that are of concern to this paper are the end-to-end header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted,

	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS

	message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. "A plethora of terminal commands – display memory, alter

	memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging. ... PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23 "*Adaptive Power Control*: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmissions from various-distanced PRs at each receiver, to mitigate the 'near-far' problem." Jubin page 31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected

	devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its

	most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "It is the local broadcast nature of packet radio that gives the PRNET its unique networking characteristic: a PR's transmission is received by all PRs within line-of-sight; e.g., in Fig. 2, a connecting line indicates which PR's are within line-of-sight of each other." Jubin page 22.

The '842 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. A device for communicating information, the device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	'The PRNET system comprises: • The PRNET subnet, which consists if the packet radios. The PRNET subnet provides the means of interconnecting q community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time. The primary component of the packet radio communication network system is the packet radio." Jubin page 22 "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote computer." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging." Jubin page 23.
an interface circuit for communicating with a central location; and	"The LPR consists of both digital and RF subsystems. " Jubin

	page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and the PR." Jubin page 22.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"The LPR consists of both digital and RF subsystems. " Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote computer." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging." Jubin page 23. "Each packet radio gathers and maintains enough information about network topology so that it can make in dependent decisions about how to route data through the network to any destination, even before it is given a packet to deliver or

	forward." Jubin page 23. "The PRNET provided a dynamic addressing capability. The DARPA packet radio network's device-to-PR mapping is known as logical addressing." Jubin page 25. "In Fig. 6, Device 1 launches a packet destined for distant Device 2. The packet is sent across the wire interface to PR L, which uses its device table to map Device-id 2 to its attached PR(*N*)." Jubin page 25. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern in this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header*: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25.
7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The above contentions for claim 1 are hereby incorporated by reference. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern in this paper are the end-to-end (ETE)

	header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header*: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The above contentions for claim 1 are hereby incorporated by reference. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern in this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header*: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25.
16. A device for communicating information, the device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.
a processor; and	"The LPR consists of both digital and RF subsystems." Jubin page 22. "The digital subsystem controls the routing and flow of packets

	between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22.
a memory, the memory comprising logical instructions that when executed by the processor are configured to cause the device to:	"Each packet radio gathers and maintains enough information about network topology so that it can make independent decisions about how to route data through the network to any destination, even before it is given a packet to deliver or forward. The network information is stored in three tables: • neighbor table • tier table • device table These tables are established by the packet radio upon initialization, and are updated automatically by the PRs as the topology changes. In the following paragraphs, we describe how the tables are established, maintained, and used. *A. Neighbor Table* After a PR (say PR L in Fig. 2) has been powered on, and has loaded its protocol software into RAM, it begins the process of establishing and maintaining local connectivity." Jubin page 23.

wirelessly transmit a signal comprising instruction data for delivery to a network of addressable low-power transceivers;	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote computer." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging." Jubin page 23
establish a communication ink between at least one low-power transceiver in the network of addressable low-power transceivers and a central location based on an address included in the signal, the communication link comprising one or more low-power transceivers in the network of addressable low-power transceivers; and	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination." Jubin page 22. "*A. Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. …The packet headers that are of concern in this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …*Routing Header*: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25.
receive one or more low-power RF signals and communicate information contained within the signals to the central location along with a unique transceiver identification number over the communication link.	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding network behavior." Jubin page 23.

17. A device for communicating information, the device comprising:	"The PRNET provides, via a common radio channel, the exchange of data between computers that are geographically separated." Jubin page 21.
a low-power transceiver that is configured to wirelessly receive a signal including an instruction data from a remote device;	"The PRNET system comprises: • The PRNET subnet, which consists if the packet radios. The PRNET subnet provides the means of interconnecting q community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time. The primary component of the packet radio communication network system is the packet radio." Jubin page 22 "Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire interface." Jubin page 22.
an interface circuit for communicating with a central location;	"The LPR consists of both digital and RF subsystems." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "A host computer may be directly interfaced to a PR. If a user wishes to send data across the PRNET from a terminal or host that does not run the required protocols, a Network Interface Unit (NIU) [8], Fig. 3, may be used between the terminal or host and

	the PR." Jubin page 22
a controller coupled to the interface circuit and the low-power transceiver, the controller being configured to establish a communication link between the remote device and the central location using address-indicative data included in the signal;	"The LPR consists of both digital and RF subsystems." Jubin page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel." Jubin page 22. "Each packet radio gathers and maintains enough information about network topology o that it can make in dependent decisions about how to route data through the network to any destination, even before it is given a packet to deliver or forward." Jubin page 23. "Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. … The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 23. "The PRNET provided a dynamic addressing capability. The DARPA packet radio network's device-to-PR mapping is known as logical addressing." Jubin page 23. "In Fig. 6, Device 1 launches a packet destined for distant device 2. The packet is sent across the wire interface to PR L, which uses its device table to map Device-id 2 to its attached PR(N)." Jubin page 23.
the controller further configured to receive one or more data signals from the central location via the interface circuit and communicate information contained within the signals to the remote device.	"Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wire

	interface." Jubin page 22. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote computer." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.-are available for local debugging." Jubin page 23.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Jubin

The '893 Patent – Claim	J. Jubin et al., "*The DARPA Packet Radio Network Protocols,*" Proceedings of the IEEE, Vol. 75, No. 1, January 1987.
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, page 22. "The primary component of the packet radio communication network system is the packet radio. … This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "Since the DARPA PRNET is a part of the DARPA Experimental Internet System [7], the devices are responsible for running the DoD-standard internetwork-, transport-, and application-level protocols (IP, TCP, and TELNET). These protocols ensure that the end-to-end communication between hosts is reliable and robust, and allow hosts on the PRNET to communicate with computers on various other packet-switched satellite, terrestrial, radio, and local area networks that also participate in the DARPA Internet." Jubin, page 22 "The PRNET can also be accessed from other networks via an Internet gateway." Jubin, page 23.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Jubin

	 Fig. 4. Packet radio network in the Internet. "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin, page 23. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin, page 23.
a plurality of transceivers, each transceiver being in	"The PRNET system comprises:

communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	• The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, page 22. "This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6, Jubin pages 22 and 25. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B)." Jubin page 25. "*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the

	destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, p. 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	*"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	*"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or

	destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information

	is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59.

	'252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	*"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the

	destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a command indicator comprising a command code;	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet

	network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B). … Forwarding is accomplished via information read from the device and tier tables (Sections III-B and III-C) and from the packet headers (Section IV-A). Forward error correction increases the probability of error-free reception, and cyclic redundancy checksums prevent, with high probability, the forwarding of packets that are not error-free (Section IV-C)." Jubin page 25.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and

	receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network

	service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. 	Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers;	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc. – are available for local debugging." Jubin page 23. "Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
a sensor detecting a second condition and outputting a sensed data signal to the transceiver; and	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
an actuator controlling a third condition and receiving control signals from the transceiver.	"*Adaptive Power Control*: The hardware provides the software the capability to select, on a packet-by-packet basis, attenuation to the nominal 5-W transmitted signal of 0 to 24 dB in 8-dB steps. This feature can be used to decrease or increase network connectivity or to match the signal power of transmission from various-distanced PRs at each receiver, to mitigate the "near-far" problem." Jubin page 31.
17. A system for communicating commands and sensed data	"The PRNET provides, via a common radio channel, the

between remote devices, the system comprising:	exchange of data between computers that are geographically separated." Jubin page 21.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The PRNET system comprises: • The PRNET subnet, which consists of the packet radios. The PRNET subnet provides the means of interconnecting a community of users. • The collection of devices (host computers and terminals), each attached to a packet radio via a wire high-level data link control (HDLC) interface, that wish to exchange data in real time." Jubin, page 22. "This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. Figs. 2 and 6. Jubin page 22 and 25. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B). Jubin page 25.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Jubin

	"*ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"This packet radio equipment has been designated the Low-cost Packet Radio (LPR) [5], Fig. 1. The LPR consists of both digital and RF subsystems." Jubin, page 22. "The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"*A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-

	B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23.
wherein all messages comprise at least one packet, the packet having a predetermined format;	"A.Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. … The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header." Jubin page 25.
wherein the predetermined format comprises:	
a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	*"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding

	through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service

	module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39.

	"FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to

	addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a sender address comprising an unique address of the sender;	*"ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is used to update the PR's stored-device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B)." Jubin page 25.
a command indicator comprising a command code;	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "PRs can also be loaded and debugged from a remote host computer. All commands available to a local operator are available to a remote operator." Jubin page 23.

	"Another host computer function called the Network Monitor is used to aid in observing and analyzing the PRNET. Each PR continuously gathers measurements on bidirectional link quality, nodal capacity, and route characteristics. The Network Monitor will collect data from each of the packet radios and display them graphically to aid the network designers in characterizing and understanding the network behavior." Jubin page 23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent

	week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	"Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B). … Forwarding is accomplished via information read from the device and tier tables (Sections III-B and III-C) and from the packet headers (Section IV-A). Forward error correction increases the probability of error-free reception, and cyclic redundancy checksums prevent, with high probability, the forwarding of packets that are not error-free (Section IV-C)." Jubin page 25. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Jubin, it would have been obvious to a person ordinary skill in the art to combine and/or modify Jubin with the teachings of one or more of the additional references teaching this limitation as cited below. U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. an error detector that is a redundancy check error detector; and	"Forward error correction increases the probability of error-free

	reception, and cyclic redundancy checksums prevent, with high probability, the forwarding of packets that are not error-free (Section IV-C)." Jubin page 25.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"The digital subsystem controls the routing and flow of packets between PRs while the RF subsystem transmits and receives packets over the radio channel. … Each PR is responsible for receiving a packet and relaying it on to a PR that is one hop closer to the final destination. The packets can be routed either to another PR over the radio channel or to an attached device (i.e., host computer or terminal) via the wireless interface." Jubin page 22. "Instead, generally speaking, a packet traverses a single path through the network, and is acknowledged at every packet radio along the path (Section IV-B). … Forwarding is accomplished via information read from the device and tier tables (Sections III-B and III-C) and from the packet headers (Section IV-A)." Jubin page 25. "Forwarding: Packets are forwarded over a single path through the PRNET by each packet radio using the information in the packet's headers and in its own device and tier tables. Each PR uses this information, first, to decide whether it should be the one to transmit the packet on, second, to update the routing header before transmitting the packet on, and third, to update its own tables." Jubin page 26. Retransmission: If a PR, say L, that has forwarded a packet does not receive an acknowledgement within a certain interval, it retransmits the packet." Jubin page 26.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Burchfiel

The '492 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a receiver address comprising a scalable address of at least one remote device;	"Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped doff by lower level programs on reception. Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Burchfiel

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more

	commercialized and proposing extensions for IP addressing.
a command indicator comprising command code;	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted,

	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through

	appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error message to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers,

	which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet."

	'252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a controller associated with a remote device comprising a	"The set of functions which appear in common in a station,

transceiver configured to send and receive wireless signals, the remote device configured to send a preformatted message comprising the receiver address, a command indicator, and the data value via the transceiver to at least one other remote device.	repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3, Burchfiel pages 246-247. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or

	deposit words in the PRU's microprocessor memory, and the RU responds with a positive acknowledgement for each command." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command

	or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by reference.
a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Each PRU (station, repeater, terminal) has a unique, hardwired I.D." Burchfiel page 247.
a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the station providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped doff by lower level programs on reception. Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to

	addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from at least one other transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "STATION CONTROL FUNCTIONS The control functions performed by a station include initialization of the PRN, dynamic routing changes, and multi-station coordination. Initialization of the PRN includes the following

	steps: 1. Measurement of RF propagation connectivity between all stations and repeaters." Burchfiel page 247.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
providing a receiver to receive at least one message;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve standalone as a repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal." Burchfiel page 246. Figure 1, Burchfiel page 247.
wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "They also require error control because of message interference

	in the shared broadcast communication channel. The error control mechanisms selected are: 1.A sequence number in each packet to permit detection of missing or duplicative packets. 2.An end-to-end positive acknowledgement for packets which arrive successfully. 3.A source timeout which causes periodic retransmission of unacknowledged packets." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3, Burchfiel page 246-247. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)."

	Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute

	jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data

	transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information

	originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more

	commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination. Such connections require flow control to prevent a source from overloading the network and causing serious congestion. They also require error control because of message interference in the shared broadcast communication channel." Burchfiel page 246. "All labeled repeaters that hear a search packet on the first hop forward it via their established route to every station that had labeled the receiving repeater. All unlabeled repeaters ignore search packets." Burchfiel page 247. "They also require error control because of message interference in the shared broadcast communication channel. The error control mechanisms selected are:

	1.A sequence number in each packet to permit detection of missing or duplicative packets. 2.An end-to-end positive acknowledgement for packets which arrive successfully. 3.A source timeout which causes periodic retransmission of unacknowledged packets." Burchfiel page 246.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245 "Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246.

	"STATION CONTROL FUNCTIONS The control functions performed by a station include initialization of the PRN, dynamic routing changes, and multi-station coordination. Initialization of the PRN includes the following steps: 1. Measurement of RF propagation connectivity between all stations and repeaters." Burchfiel page 247.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers

	that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and

	receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network

	service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for

	Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contentions for claim 8 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the

	station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends command over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger. " Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be

	programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contentions for claim 8 are hereby incorporated by reference. "They also require error control because of message interference in the shared broadcast communication channel. The error control mechanisms selected are: 1.A sequence number in each packet to permit detection of missing or duplicative packets. 2.An end-to-end positive acknowledgement for packets which arrive successfully. 3.A source timeout which causes periodic retransmission of unacknowledged packets." Burchfiel page 246.
14. A wireless communication device for use in a communication system to communicate command and sensed data between	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of

remote wireless communication devices, the wireless communication device comprising:	information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a transceiver configured to send and receive wireless communications; and	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve standalone as a repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal." Burchfiel page 246.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each

	direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figures 2 and 3, Burchfiel pages 246-247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted,

	if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for

	routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed

	through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to

	individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message

	includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "When any repeater detects a significant routing event, e.g., failure of some previously established route or a request from a terminal to enter a network, the repeater forwards this information over its control connection to the nearest station." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's." Burchfiel page 250.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one	The above contentions for claim 14 are hereby incorporated by reference.

received message is a duplicate message and determine a location from which the duplicate message originated.	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination. Such connections require flow control to prevent a source from overloading the network and causing serious congestion. They also require error control because of message interference in the shared broadcast communication channel." Burchfiel page 246. "All labeled repeaters that hear a search packet on the first hop forward it via their established route to every station that had labeled the receiving repeater. All unlabeled repeaters ignore search packets." Burchfiel page 247. "They also require error control because of message interference in the shared broadcast communication channel. The error control mechanisms selected are: 1.A sequence number in each packet to permit detection of

	missing or duplicative packets. 2.An end-to-end positive acknowledgement for packets which arrive successfully. 3.A source timeout which causes periodic retransmission of unacknowledged packets." Burchfiel page 246.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contentions for claim 14 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends command over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger. " Burchfiel page 250.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference.

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Burchfiel

	"Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing a store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve standalone as a repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal." Burchfiel page 246. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.

	"Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figures 2 and 3, Burchfiel pages 246-247.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245.
wherein the preformatted message comprises at least one packet,	"Reliable data transmission between PRN data sources and sinks

wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process and destination process, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "They also require error control because of message interference in the shared broadcast communication channel. The error control mechanisms selected are: 1.A sequence number in each packet to permit detection of missing or duplicative packets. 2.An end-to-end positive acknowledgement for packets which arrive successfully. 3.A source timeout which causes periodic retransmission of unacknowledged packets." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1

	routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3, Burchfiel page 246-247. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in

	the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

Exhibit P2 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Burchfiel

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection

	bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class

	address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message

	format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "When any repeater detects a significant routing event, e.g., failure of some previously established route or a request from a terminal to enter a network, the repeater forwards this information over its control connection to the nearest station." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's." Burchfiel page 250.
21. The communication device of claim 20, wherein the	The above contentions for claim 20 are hereby incorporated by

transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends command over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped doff by lower level programs on reception. Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491

	(“the ‘491 patent”), U.S. Patent No. 7,027,773 (“the ‘773 patent”), U.S. Patent No. 6,100,817 (“the ‘817 patent”), U.S. Patent No. 5,874,903 (“the ‘903 patent”) or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated.” Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. *“A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS

	message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network

	service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP

	addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing a store-and-forward function on the radio broadcast channel." Burchfiel

	page 245.
a transceiver configured to send and receive wireless communications; and	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a packet radio unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve standalone as a repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal. The additional functions shown for terminal may either be implemented in a separate microprocessor or provided in a separate memory partition within the terminal's PRU, timesharing its microprocessor for economy." Burchfiel page 245-246. Figure 1, Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure." Burchfiel page 246.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-

message.	forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor." Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3, Burchfiel pages 246-247. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the RU responds with a positive acknowledgement for each command." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

	"A.Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by

	monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be

	used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet."

	'252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

The '611 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions

	implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. "A level-3 debugging protocol has been defined which supports

	debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
5. A system for monitoring remote devices, comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel

	page 245.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
one or more additional wireless transmitters each electrically	"A packet radio network is a digital broadcast channel, fixed and

interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and

located device.	control connections).” Burchfiel page 245. “In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed.” Burchfiel page 245. “The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1.” Burchfiel page 245. “The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio.” Burchfiel page 245. “Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET.” Burchfiel page 246. Figure 1, Burchfiel page 246.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. “Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET.” Burchfiel page 246.

8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
9. A system for controlling a remote device comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a target remote device having an actuator to be controlled;	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. "The debug program is another independent process. On request fro the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S.

	Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging,

	and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
a wireless transmitter coupled with the gateway for transmitting a	"A packet radio network is a digital broadcast channel, fixed and

wireless signal that contains the control signal;	mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-

	forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. "The additional functions shown for terminal may either be implemented in a separate microprocessor or provided in a separate memory partition within the terminal's PRU, timesharing its microprocessor for economy." Burchfiel page 246.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging."

	Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system

	programmer." Burchfiel page 248. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. "The debug program is another independent process. On request fro the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions." Burchfiel page 250.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations

	providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot)." Burchfiel page 250. "The debug program is another independent process. On request fro the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions." Burchfiel page 250.

12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Burchfiel

The '692 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. A system for remote data collection, assembly, and storage comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246.

	Figure 1, Burchfiel page 246.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.

	Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of the newly-discovered device." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's." Burchfiel page 250.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the programs which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which

	controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has

	been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249.
8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's." Burchfiel page 250.
11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"Figure 4 shows the hardware organization of our prototype station: it is a PDP-11 processor interfaced to a packet radio unit. In the initial tests, it will also be connected as a gateway to the ARPANET." Burchfiel page 249. Figure 4, Burchfiel page 249.

12. The system as defined in claim 1, wherein the gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	The above contentions for claim 1 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed

	over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways:

	1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks.…" Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
14. The system as defined in claim 1, wherein the WAN is a dedicated Intranet.	The above contentions for claim 1 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "This applies not only to host-host protocol, but also to higher level protocols such as TELNET, file transfer, and remote job entry. All that is required is a conversion program for the high-level protocol of interest, interposed between the PRN connection and the ARPANET connection." Burchfiel page 249.
24. A method for controlling a system comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital

	terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
remotely collecting data from at least one sensor;	"The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's." Burchfiel page 250.
processing the data into a radio-frequency (RF) signal;	"One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249.
transmitting the RF signal, via a relatively low-power transceiver, to a gateway;	Figure 1, Burchfiel page 246. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It

	sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of the newly-discovered devices. This procedure is iterated until every station and repeater in the area has been configured into the network. At this point, the control process has an open control connection to every other station and repeater in the PRN." Burchfiel page 250.
translating the data in the RF signal into a network transfer protocol;	"Figure 4 shows the hardware organization of our prototype station: it is a PDP-11 processor interfaced to a packet radio unit. In the initial tests, it will also be connected as a gateway to the ARPANET." Burchfiel page 249. Figure 4, Burchfiel page 249. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by the at least one sensor by generating an appropriate control signal;	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
sending the control signal via the network to the gateway,	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory,

	and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
translating the control signal from a network transfer protocol into an RF control signal;	"Figure 4 shows the hardware organization of our prototype station: it is a PDP-11 processor interfaced to a packet radio unit. In the initial tests, it will also be connected as a gateway to the ARPANET." Burchfiel page 249. Figure 4, Burchfiel page 249.
transmitting the RF control signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246.
receiving the RF control signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246.

	"One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246.
translating the received RF control signal into an analog signal; and	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
applying the analog signal to an actuator to effect the desired system response.	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
25. The method of claim 24, wherein the RF signal contains a concatenation of information comprising encoded data information and transmitter identification information from an originating transmitter.	The previous contentions for claim 24 are herby incorporated by reference. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the programs which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and

	stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
26. The method of claim 25, wherein the step of transmitting the RF signal is further performed by at least one transceiver, wherein the transceiver is configured to concatenate a transceiver identification code to the RF signal.	The previous contentions for claim 25 are herby incorporated by reference. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is

	programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
27. The method of claim 25, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The previous contentions for claim 25 are herby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Burchfiel

28. The method of claim 25, wherein the steps of translating and applying the received RF control signal are performed only by an identified transceiver electrically integrated with an actuator.	The previous contentions for claim 25 are herby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250.
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 25 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
30. The method of claim 25, wherein the network is an Intranet.	The above contentions for claim 25 are hereby incorporated by reference. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 1, Burchfiel page 246. "This applies not only to host-host protocol, but also to higher level protocols such as TELNET, file transfer, and remote job entry. All that is required is a conversion program for the high-level protocol of interest, interposed between the PRN connection and the ARPANET connection." Burchfiel page 249.
31. The method of claim 25, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 25 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23.

	'217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses:

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
32. A system for monitoring remote devices comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.

at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a low-power radio-frequency (RF) signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "A level-3 debugging protocol has been defined which supports debugging of

	remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
at least one gateway connected a wide area network (WAN) configured to receive and translate the RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and

	performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249.
36. The system defined in claim 32, wherein the	The above contentions for claim 32 are hereby incorporated by reference.

gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 3. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 4. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol

	mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. '817 patent, 6:1-8.
38. The system defined in claim 32, wherein the WAN is a dedicated Intranet.	The above contentions for claim 32 are hereby incorporated by reference. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 1, Burchfiel page 246. "This applies not only to host-host protocol, but also to higher level protocols such as TELNET, file transfer, and remote job entry. All that is required is a conversion program for the high-level protocol of interest, interposed between

	the PRN connection and the ARPANET connection." Burchfiel page 249.
42. A system for controlling remote devices comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246.

	Figure 1, Burchfiel page 246.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.

	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions

	made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the programs which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.

46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example:

Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,437,692 based on Burchfiel

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.

51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol

	mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23. ‘217 patent discloses: “The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal

	will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in

	the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
53. The system as defined in claim 49, wherein the WAN is a dedicated Intranet.	The above contentions for claim 49 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
54. The system as defined in claim 49, wherein the at least one gateway is connected to the WAN by a network selected from the group consisting of a telecommunications network, private radio-frequency network, and a computer network.	Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. "Figure 4 shows the hardware organization of our prototype station: it is a PDP-11 processor interfaced to a packet radio unit. In the initial tests, it will also be connected as a gateway to the ARPANET." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
55. A method of collecting information and providing data services comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections). Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve standalone as a repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal. The additional functions shown for terminal may either be implemented in a separate microprocessor or provided in a separate memory partition within the terminal's PRU." Burchfiel page 245-246. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page

	245. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the programs which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247. "When any repeater detects a significant routing event, e.g., failure or some previously established route or a request from a terminal to enter the network, the repeater forwards this information over its control connection to the nearest station. Burchfiel page 250.
adaptively configuring at least one transmitter with the data translator, wherein the transmitter converts the information signal into a low-power RF signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and

	repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the station providing initialization and centralized control of parameters for terminal tracking. … Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between the source process ad destination process, and performing end-to-end error detection and correction over this noisy channel. Burchfiel page 245. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"When a terminal comes on-line, the station establishes a data connection to it and provides an 'information service' to assist in completing the connection to the destination device, which may be either in the PRN or in the ARPANET." Burchfiel page 250.
granting client access to the computer.	"When a terminal comes on-line, the station establishes a data connection to it

	and provides an 'information service' to assist in completing the connection to the destination device, which may be either in the PRN or in the ARPANET." Burchfiel page 250. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249.

	Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102.

	The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below.

	However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 55 are hereby incorporated by reference. Figure 1, Burchfiel page 246. '817 patent, 6:1-8.
60. A method for controlling an existing control system with a local controller comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
adaptively configuring a data translator disposed between and in communication with both a local controller and a wireless transceiver, wherein the data translator is configured to translate the local	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.

controller data stream into an information signal consisting of a transceiver identification code and a concatenation of function codes, the data translator further configured to translate control signals from the wireless transceiver into local controller recognized control signals;	Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not

	fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "A similar mechanism permits centralized collection of traffic statistics, both through examination of counters in PRU memory and through centralized reception of special status conditions such as "trace packets" moving through the network. Burchfiel page 248. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. Burchfiel page 250.
processing the data into an RF signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and

	repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
transmitting the RF signal to a gateway;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A similar mechanism permits centralized collection of traffic statistics, both through examination of counters in PRU memory and through centralized reception of special status conditions such as "trace packets" moving through the network. Burchfiel page 248. "Once the station has collected a et of traffic statistics, it will normally forward these measurements to a service host for detailed statistical analysis, logging and plotting." Burchfiel page 248.
translating the data in the RF signal into a network transfer protocol;	Figure 1, Burchfiel page 246. "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249.

	Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by at least one sensor by generating an appropriate control signal;	"Once the station has collected a set of traffic statistics, it will normally forward these measurements to a service host for detailed statistical analysis, logging and plotting." Burchfiel page 248. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
sending the control signal via the network to the gateway;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "A packet radio network is a digital broadcast channel, fixed and mobile digital

	terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination." Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246.
translating the control signal from a network transfer protocol into an RF control signal;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Burchfiel

The '732 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. "Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246.

	Figure 1, Burchfiel page 246. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Burchfiel

at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	"Our prototype station has the additional station functions implemented in a Digital Equipment Corp. PDP-11, which is also interfaced to the ARPANET." Burchfiel page 246. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. "For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. " Burchfiel page 249. Figure 4, Burchfiel page 249. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap

	conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23

	U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be

	performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245.

information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247.
a data controller operatively coupled to the transceiver and the sensor, the data controller	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control

configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. "The additional functions shown for terminal may either be implemented in a separate microprocessor or provided in a separate memory partition within the terminal's PRU, timesharing its microprocessor for economy." Burchfiel page 246.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers

	data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23

	U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the

	MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions.

	When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
17. The device of claim 13**,** wherein the data controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed	The above contentions for claim 13 are hereby incorporated by reference. "The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control

data and the unique identification code	connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements."

	'903, 4:23-31.
18. The device of claim 13, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the data controller can implement.	The above contentions for claim 13 are hereby incorporated by reference. "A similar mechanism permits centralized collection of traffic statistics, both through examination of counters in PRU memory and through centralized collection of special status conditions such as "trace packets" moving through the network." Burchfiel page 248. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Burchfiel

19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the command.	The above contentions for claim 13 are hereby incorporated by reference. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings

	of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is

	programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly…." Burchfiel page 246. Figure 3, Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "In addition to the communications support, the terminal must also have a terminal handler program which manages terminal input and output buffers and performs translation of format effector characters as needed." Burchfiel page

	245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. These functions are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. "The additional functions shown for terminal may either be implemented in a separate microprocessor or provided in a separate memory partition within the terminal's PRU, timesharing its microprocessor for economy." Burchfiel page 246. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the

	MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31, further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	The above contentions for claim 31 are hereby incorporated by reference. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "Our prototype station has the additional station function implemented in a Digital Equipment Corp. PDP-11, which is also interfaced with the ARPANET." Burchfiel page 246.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,013,732 based on Burchfiel

	"When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1.For communication with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway…." Burchfiel page 249. "Figure 4 shows the hardware organization of our prototype station: it is a PDP-11 processor interfaced to a packet radio unit. In the initial tests, it will also be connected as a gateway to the ARPANET." Burchfiel page 249." "When a terminal comes on-line, the station establishes a data connection to it. And provides an 'information service' to assist in completing the connection to the destination device, which may be either in the PRN or in the ARPANET." Burchfiel page 250. "Finally, the PRN TELNET process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet

	gateway." Jubin page 23. '217 patent discloses: "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. '650 patent discloses "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.

	'773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "The debug program is another independent process. On request from the

	maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred

	embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "The 'function fields' provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel pag3 247. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator."

	Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to	The above contentions for claim 31 are hereby incorporated by reference. "A similar mechanism permits centralized collection of traffic statistics, both

the sensor.	through examination of counters in PRU memory and through centralized collection of special status conditions such as "trace packets" moving through the network." Burchfiel page 248. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g.. hardware failure. These functions made it possible to do centralized software maintenance of remote, unattended repeaters. The maintenance terminal of the station will normally be attended by an operator or system programmer." Burchfiel page 248. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. There are also commands for setting traps on anomalous program conditions. When one these conditions is encountered … it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,754,780 based on Burchfiel

The '780 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. In a system comprising a plurality of wireless devices, a device comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio. It will serve as a standalone repeater; addition of the station interface hardware and software option converts it to a station; addition of the terminal interface hardware and software option converts it to a terminal." Burchfiel pages 245-246.

	Figure 1, Burchfiel page 246. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking." Burchfiel page 245.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (salve) routine in each repeater. These features are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the

	station's PRU. Its ends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. Its ends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250.

	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off,

	and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. Its ends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request

	from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent

	week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module

	to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8,754,780 based on Burchfiel

	repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (salve) routine in each repeater. These features are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246.

7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23

	U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "Initialization of the PRN includes the following steps: …2)Configuring the PRN by loading each repeater with routing parameters which control the packet store-and-forward program. These parameters specify forwarding of packets 9in the direction of minimum distance] to the next repeater within "earshot." Burchfiel page 247. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establish control connections to the PRU's of the newly-discovered devices." Burchfiel page 250.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8.908,842 based on Burchfiel

The '842 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. A device for communicating information, the device comprising:	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission is each direction piggybacked into the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As Measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250.

	"The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
an interface circuit for communicating with a central location; and	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the station providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of

	hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters with stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor. " Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission is each direction piggybacked into the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly:…." Burchfiel page 246. Figure 3, Burchfiel page 247. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 8.908,842 based on Burchfiel

	"In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As Measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250.
7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The above contentions for claim 1 are hereby incorporated by reference "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly:…." Burchfiel page 246. Figure 3, Burchfiel page 247.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The above contentions for claim 1 are hereby incorporated by reference "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly:…." Burchfiel page 246.

	Figure 3, Burchfiel page 247. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
16. A device for communicating information, the device comprising:	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.
a processor; and	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters with stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor. " Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.

	Figure 1, Burchfiel page 246.
a memory, the memory comprising logical instructions that when executed by the processor are configured to cause the device to:	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245.
wirelessly transmit a signal comprising instruction data for delivery to a network of addressable low-power transceivers;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission is each direction piggybacked into the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by

	PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
establish a communication link between at least one low-power transceiver in the network of addressable low-power transceivers and a central location based on an address included in the signal, the communication link comprising one or more low-power transceivers in the network of addressable low-power transceivers; and	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process

	which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
receive one or more low-power RF signals and communicate information contained within the signals to the central location along with a unique transceiver identification number over the communication link.	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "Each PRU (station, repeater, terminal) has a unique, hardwired I.D." Burchfiel page 247. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As

	measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory and by receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
17. A device for communicating information, the device comprising:	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.
a low-power transceiver that is configured to wirelessly receive a signal including an instruction data from a remote device;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245.

	Figure 1, Burchfiel page 246. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission is each direction piggybacked into the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As Measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250. Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each

	command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.
an interface circuit for communicating with a central location;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the station providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is provided in its IMP-16 microprocessor." Burchfiel page 245. "The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.
a controller coupled to the interface circuit and to the low-power transceiver, the controller being configured to establish a communication link between the remote device and the central location using address-indicative data included in the signal;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters with stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is

	provided in its IMP-16 microprocessor. " Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission is each direction piggybacked into the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. Figure 2, Burchfiel page 246. "The protocols of the Packet Radio Network are layered or hierarchical. … Figure 3 shows this layering explicitly:…." Burchfiel page 246. Figure 3, Burchfiel page 247. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). As Measurement information comes back on this connection, the control process fills in entries in the connectivity matrix, and establishes control connections to the PRU's of newly-discovered devices." Burchfiel page 250.
the controller further configured to receive one or more data signals from the central location via the interface circuit and	"The statistics collection module is another independent process which gathers data both by examining PRU memory and by

communicate information contained within the signals to the remote device.	receiving statistics trap condition spontaneously emitted by PRU's." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command. There are also commands for setting traps on anomalous program conditions. When one of these conditions is encountered (assuming the PRU is still operational) it sends the appropriate trap code over the debugging connection to the debugger." Burchfiel page 250.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Burchfiel

The '893 Patent – Claim	J. Burchfiel et al., *"Functions and structure of a packet radio station,"* National Computer Conference, 1975.
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and erro detection for transmission of the packet from one PRU to the next." Burchfiel page 246.

	Figure 3, Burchfiel page 247. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor. " Burchfiel page 245. "Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3. Burchfiel pages 246-247.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"Flow control is established by the convention that the sender can only send up to N packets ahead of the last packet which was acknowledged. Equivalently, a source may not have more than N packets 'in the pipeline' at one time. To keep the repeater code as

	simple as possible, N should be equal to one (packet-at-a-time) for repeater control connections. This protocol is a simplified subset of the protocol developed by Cerf and Kahn [7] for internetwork communications. The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information as levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly; the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based in a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	*Id.* "Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. Figure 2, Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.

Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Burchfiel

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	*Id.* "Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. Figure 2, Burchfiel page 246. Figure 3, Burchfiel page 247.
a command indicator comprising a command code;	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel

	page 248. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute

	jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

at least one data value comprising a scalable message; and	*Id.* Figure 2, Burchfiel page 246. Figure 3, Burchfiel page 247.
an error detector comprising a redundancy check error detector; and	*Id.* "Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. Figure 3, Burchfiel page 247.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages.	*Id.* "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. The functions are shown in Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 2, Burchfiel page 246. In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the

	station's PRU. It sends commands over the connection to trigger connectivity measurements (exploratory pacekts which request answerback from stations and repeaters within earshot). As measurement information comes back on the connection, the control process fills entries in the connectivity matrix, and established control connections to the PRU's of the newly discovered devices." Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.
2. The system of claim 1, wherein the plurality of transceivers further comprise at least one integrated transceiver, wherein the integrated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers; and	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the

	PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.
a sensor detecting a condition and outputting a sensed data signal to the transceiver.	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250.
3. The system of claim 2, wherein the at least one integrated transceiver receives the preformatted command message requesting sensed data, confirms the receiver address as its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet, wherein the packets are equal to the number of segments.	The above contentions for claim 2 are hereby incorporated by reference. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each

	command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of

Exhibit P3 – Invalidity Chart for U.S. Patent No. 6,914,893 based on Burchfiel

	the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers;	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250
a sensor detecting a second condition and outputting a sensed data signal to the transceiver; and	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the

	PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250
an actuator controlling a third condition and receiving control signals from the transceiver.	"The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"A packet radio network is a digital broadcast channel, fixed and mobile digital terminals which are sources and sinks of information, stations which provide centralized routing control and interconnections to other networks, and repeaters which provide area coverage for mobile terminals by performing store-and-forward function on the radio broadcast channel." Burchfiel page 245.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of	"The set of functions which appear in common in a station, repeater, and terminal are identified in Figure 1 as a Packet Radio

transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	Unit, or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, page 246. "The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information at levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 'Radio Hop' protocol which provides broadcast synchronization and erro detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The dynamic packet routing capability (packet store-and-forward) is programmed in the repeaters, with the stations providing initialization and centralized control of parameters for terminal tracking. The programmable capability of the repeater is providing in its IMP-16 microprocessor. " Burchfiel page 245.

	"Since most expected uses of the PRN will require bi-directional communication, the PRN connection is bi-directional, with flow control and error control information for data transmission in each direction piggybacked onto the data flow in the opposite direction. This arrangement is depicted in Figure 2." Burchfiel page 246. "Figure 3 shows this layering explicitly: the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based on a level 0 "Radio Hop" protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3. Burchfiel pages 246-247.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "Flow control is established by the convention that the sender can only send up to N packets ahead of the last packet which was acknowledged. Equivalently, a source may not have more than N packets 'in the pipeline' at one time. To keep the repeater code as simple as possible, N should be equal to one (packet-at-a-time) for repeater control connections. This protocol is a simplified subset of the protocol developed by Cerf and Kahn [7] for internetwork communications. The protocols of the Packet Radio

	Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information as levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly; the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based in a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figs. 2 and 3. Burchfiel pages 246-247. "Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247.
sender address comprising the unique address of the sending transceiver;	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "Flow control is established by the convention that the sender can only send up to N packets ahead of the last packet which was acknowledged. Burchfiel page 246. Figure 2, Burchfiel page 246. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs'

	stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command

	station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first,

	broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a

	network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing

	explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector;	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. Figure 3, Burchfiel page 247.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages; and	*Id.* "The programs which provide centralized monitoring, debugging, and statistics collection are located in the station, with a small (slave) routine in each repeater. The functions are shown in

	Figure 1." Burchfiel page 245. Figure 1, Burchfiel page 246. Figure 2, Burchfiel page 246. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). " Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250
wherein at least one of the plurality of transceivers further sends preformatted emergency messages.	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1.

	U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
18. The system of claim 17, wherein the controller maintains periods of silence by not sending the preformatted command messages during predetermined time periods; and	The above contentions for claim 17 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. processing the message;	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The set of functions which appear in common in a station, repeater and terminal are identified in Figure 1 as a Packet Radio Unit , or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246.
preparing a response message;	"In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the

	station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). " Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250
receiving the response message;	"In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). " Burchfiel page 250.
processing the response message	"The programs for providing interprocess connections within the PRN must be programmed into each terminal (data connection), each repeater (control connection), and each station (data and control connections)." Burchfiel page 245. "The set of functions which appear in common in a station,

	repeater and terminal are identified in Figure 1 as a Packet Radio Unit , or PRU, which has been implemented as a standard piece of hardware and software by Collins Radio." Burchfiel page 245. Figure 1, Burchfiel page 246.
wherein all messages comprise at least one packet, the packet having a predetermined format;	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "Flow control is established by the convention that the sender can only send up to N packets ahead of the last packet which was acknowledged. Equivalently, a source may not have more than N packets 'in the pipeline' at one time. To keep the repeater code as simple as possible, N should be equal to one (packet-at-a-time) for repeater control connections. This protocol is a simplified subset of the protocol developed by Cerf and Kahn [7] for internetwork communications. The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information as levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly; the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based in a level 0 'Radio Hop' protocol which provides

	broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247.
wherein the predetermined format comprises:	
a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	"Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "Once the station has labelled all PRU's and established connections to them, the information for maintaining these connections is entered into the station's connection table. This contains the status information described above for handling the connection protocol." Burchfiel page 247. Figure 3, Burchfiel page 247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a sender address comprising an unique address of the sender;	"Each PRU (station, repeater, terminal) has a unique hardwired I.D." Burchfiel page 247. "Once the station has labelled all PRU's and established connections to them, the information for maintaining these

	connections is entered into the station's connection table. This contains the status information described above for handling the connection protocol." Burchfiel page 247. Figure 3, Burchfiel page 247.
a command indicator comprising a command code;	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. "In the PRN initialization procedure, the control process calls on the connection module to establish a control connection to the station's PRU. It sends commands over this connection to trigger connectivity measurements (exploratory packets which request answerback from stations and repeaters within earshot). " Burchfiel page 250. "The debug program is another independent process. On request from the maintenance terminal, it calls on the connection module to open a debugging connection to the PRU of interest. The debugger sends commands over this connection to examine or deposit words in the PRU's microprocessor memory, and the PRU responds with a positive acknowledgement for each

	command." Burchfiel page 250. "The statistics collection module is another independent process which gathers data both by examining PRU memory, and by receiving statistics trap conditions spontaneously emitted by the PRU's. This operation parallels the operation of the debugger described above." Burchfiel page 250. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed

	through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	Figures 2 and 3, Burchfiel page 246-247. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Burchfiel, it would have been obvious to a person ordinary skill in the art to combine and/or modify Burchfiel with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …

	Routing Header: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. an error detector that is a redundancy check error detector; and	"Reliable data transmission between PRN data sources and sinks is required in spite of errors and transmission 'collisions' on the broadcast channel. This is achieved by defining a logical entity called a 'connection' between source processes and destination processes, and performing end-to-end error detection and correction over this noisy channel." Burchfiel page 245. "Flow control is established by the convention that the sender can only send up to N packets ahead of the last packet which was acknowledged. Equivalently, a source may not have more than N packets 'in the pipeline' at one time. To keep the repeater code as simple as possible, N should be equal to one (packet-at-a-time) for repeater control connections. This protocol is a simplified

	subset of the protocol developed by Cerf and Kahn [7] for internetwork communications. The protocols of the Packet Radio Network are layered, or hierarchical. The program which deals with control information at level M passes control and data for all levels greater than M as transparent data. Conversely, the program which deals with control at level M does not see control information as levels less than M; it is inserted by lower level programs on transmission, and stripped off by lower level programs on reception. Figure 3 shows this layering explicitly; the connection protocol described above is the level 2 protocol, based on the level 1 routing protocol which controls the PRN store-and-forward routing for the packet. The routing protocol is itself based in a level 0 'Radio Hop' protocol which provides broadcast synchronization and error detection for transmission of the packet from one PRU to the next." Burchfiel page 246. Figure 3, Burchfiel page 247.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"One of the basic facilities required in the PRN is support of interprocess connections which provide reliable delivery of data from a PRN source to a PRN destination. Burchfiel page 246. "Dynamic routing changes are performed locally within the PRN by permitting a repeater to specify an alternate address for the next hop after some number of unsuccessful attempts to forward the packet along its specified route." Burchfiel page 247.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

The '492 Patent – Claim	U.S. Patent No. 6,366,217
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a receiver address comprising a scalable address of at least one remote device;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. '217 patent, Figure 21. "As shown in FIG. 21, information is transmitted in a 32 bit address and information packet to the data collection module. This 32 bit packet includes the sensor interface module's identification and the transmitted information." '217 patent 14:3-7. "The address 1456 is a 32-bit or 4-byte sensor interface module address which is transmitted to the data collection module 110." '217 patent, 14:17-18. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15.

	"After a data packet has been collected, the data will be transmitted to a data collection module or other device using Frequency Shift Keying (FSK) modulation." '217 16:6-8. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. "Data repeater module processors communicate using SLIP encapsulated Internet Protocol (IP) datagrams. An IP datagram from a data collection module processor is sent to its router (via SLIP) for transport to the destination router and its data collection

	module processor. Only the 16-but Total Length and 32-bit Destination Address fields of an IP datagram are used by the router. The following shows the general IP protocol for data repeater module communications." '217 patent, 35:56-36:25 (including tables showing Destination Address). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields).

	"The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class

	address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message

	format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a command indicator comprising command code;	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs'

	stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the

	first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385,

	module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more

	of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the

	nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from at least one other transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
providing a receiver to receive at least one message;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water

	meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for

	transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel

	page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.

	'217 patent, Figure 19.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	'217 patent, Figure 19.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header

	and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network

	service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

a transceiver configured to send and receive wireless communications; and	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48.

	"d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S.

	Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable

	fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is

	identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304

A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No.

	6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header

	and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection

	modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector;	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are

	supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor

	interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are

	approximately 8 bytes of information." '217 patent, 15:13-15.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special

	requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-

	3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more

	commercialized and proposing extensions for IP addressing.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a transceiver configured to send and receive wireless communications; and	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface

	modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. "The sensor interface modules 102 are intelligent

	communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. "Data repeater module processors communicate using SLIP encapsulated Internet Protocol (IP) datagrams. An IP datagram from a data collection module processor is sent to its router (via SLIP) for transport to the destination router and its data collection module processor. Only the 16-but Total Length and 32-bit

	Destination Address fields of an IP datagram are used by the router. The following shows the general IP protocol for data repeater module communications." '217 patent, 35:56-36:25 (including tables showing Destination Address). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,366,217

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are

	supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network

	service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that

	uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

The '661 Patent – Claim	U.S. Patent No. 6,366,217
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

	out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way

	communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
at least one gateway connected to the wide area network configured to receive and translate the select information, the	"4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	 FIG. 49
5. A system for monitoring remote devices, comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

at least one sensor adapted to generate an electrical signal in response to a physical condition;	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

retransmit the RF signal;	interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	"IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

	 FIG. 49
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems."

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	'217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	"The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
9. A system for controlling a remote device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a target remote device having an actuator to be controlled;	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to

	control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

	out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

'217 patent, 32: 23-41. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"),

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the

	factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data

	and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a

Exhibit P4 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,366,217

	processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
12. A system for remote data collection, assembly, storage, and event detection and	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor

reporting, comprising:	interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other

	module." '217 patent, 46:11-16.
a plurality of non-earth orbiting transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

The '692 Patent – Claim	U.S. Patent No. 6,366,217
1. A system for remote data collection, assembly, and storage comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The data collection module will gather the information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217 patent, 4:62-66. "2. The Data Collection Module a.. Overview The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for a RF signal modulated with a particular format. Once a valid signal is identified, the receiver

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	stops hopping and decodes the entire data packet which is passes along CPU module for collection and evaluation." '217 patent, 18:45-55. "The data collection module 110 is a local, intelligent, data concentrator residing at or near the location of the sensor interface modules 102. The data collection module 110 act as the focal point of all the information that is collected from the sensor interface modules 102 within a monitored area such as a customer's premises and transmits this information to the host module 122 over standard communication systems 118." '217 patent, 19:17-23. "Information from the sensor interface module 102 is decoded and process in the data collection module 110 and prepared for transmission to the host module 122. The processor dynamically builds a table that stores the information received from each interface module. Information is grouped by the unique identifier assigned to each individual sensor interface module." '217 patent, 31:11-17. "An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102

	communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water

	systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. 	frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and CRC. The header information includes a preamble and a sensor interface module identifier. The preamble is designed to distinguish the transmitted information from spurious radio signals or background noise. The identifier information is designed to identify the specific sensor interface module's transmission that is being received, and to identify any other type of information such as meter-type, count-type or other information specific the device being monitored. The information signal contains the data collected by the sensor interface module." '217 patent, 13:57-67. "As shown in FIG. 21, information is transmitted in a 32 bit address and information packet to the data collection module. This 32 bit packet includes the sensor interface module's identification and the transmitted information. As shown in FIG. 21, the signal 1450 transmitted from the sensor interface module 102 consists of several sub-components. The sub-components include synchronization flags 1452, synchronization byte 1454, address 1456, input status 1458, counter 1460, and CRC bytes 1462. … The address 1456 is a 32-bit or 4-byte sensor interface module address which is transmitted to the data collection module 110." '217 patent, 14:3-18. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38.

	"The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules

	designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7.

	'217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF	The above contentions for claim 6 are hereby incorporated by reference. "d. Sensor Interface Main Body

	module." '217 patent, 46:11-16.  FIG. 49 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. control signal are performed only by an identified transceiver electrically integrated with an actuator.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 25 are hereby incorporated by reference. "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host

	module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries

	and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

	host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	32. A system for monitoring remote devices comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.

	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43.

	"d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread

'217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However,

	some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for

	communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
38. The system defined in claim 32, wherein the WAN is a dedicated Intranet.	The above contentions for claim 32 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49
42. A system for controlling remote devices comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38.

	"The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

	 FIG. 49 "The data collection module will gather the information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217 patent, 4:62-66. "2. The Data Collection Module a.. Overview The data collection module boxes are weatherproof enclosures that house data

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for a RF signal modulated with a particular format. Once a valid signal is identified, the receiver stops hopping and decodes the entire data packet which is passes along CPU module for collection and evaluation." '217 patent, 18:45-55. "The data collection module 110 is a local, intelligent, data concentrator residing at or near the location of the sensor interface modules 102. The data collection module 110 act as the focal point of all the information that is collected from the sensor interface modules 102 within a monitored area such as a customer's premises and transmits this information to the host module 122 over standard communication systems 118." '217 patent, 19:17-23. "Information from the sensor interface module 102 is decoded and process in the data collection module 110 and prepared for transmission to the host module 122. The processor dynamically builds a table that stores the information received from each interface module. Information is grouped by the unique identifier assigned to each individual sensor interface module." '217 patent, 31:11-17. "An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66.

	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio

	frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection

	module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and CRC. The header information includes a preamble and a sensor interface module identifier. The preamble is designed to distinguish the transmitted information from spurious radio signals or background

each transceiver that receives and repeats the RF signal.	noise. The identifier information is designed to identify the specific sensor interface module's transmission that is being received, and to identify any other type of information such as meter-type, count-type or other information specific the device being monitored. The information signal contains the data collected by the sensor interface module." '217 patent, 13:57-67. "As shown in FIG. 21, information is transmitted in a 32 bit address and information packet to the data collection module. This 32 bit packet includes the sensor interface module's identification and the transmitted information. As shown in FIG. 21, the signal 1450 transmitted from the sensor interface module 102 consists of several sub-components. The sub-components include synchronization flags 1452, synchronization byte 1454, address 1456, input status 1458, counter 1460, and CRC bytes 1462. … The address 1456 is a 32-bit or 4-byte sensor interface module address which is transmitted to the data collection module 110." '217 patent, 14:3-18. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

	out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38.

	"The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

	 FIG. 49 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway."

	Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2.
