	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The

	purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it

	may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

49. A system for managing an arrangement of application specific remote devices comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
a computer configured to execute a multiplicity of computer programs, each computer program executed to generate at least one control signal in response to at least one application system input, said computer integrated with a wide area network (WAN);	"The data collection module will gather the information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217 patent, 4:62-66. "2. The Data Collection Module a.. Overview The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for a RF signal modulated with a particular format. Once a valid signal is identified, the receiver stops hopping and decodes the entire data packet which is passes along CPU module

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	for collection and evaluation." '217 patent, 18:45-55. "The data collection module 110 is a local, intelligent, data concentrator residing at or near the location of the sensor interface modules 102. The data collection module 110 act as the focal point of all the information that is collected from the sensor interface modules 102 within a monitored area such as a customer's premises and transmits this information to the host module 122 over standard communication systems 118." '217 patent, 19:17-23. "Information from the sensor interface module 102 is decoded and process in the data collection module 110 and prepared for transmission to the host module 122. The processor dynamically builds a table that stores the information received from each interface module. Information is grouped by the unique identifier assigned to each individual sensor interface module." '217 patent, 31:11-17. "An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless

The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	at least one wireless relatively low-power RF transceiver per computer program configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator and a sensor;	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22.

	'217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the

	sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response; and	"5. 	module." '217 patent, 46:11-16.  FIG. 49
55. A method of collecting information and providing data services comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.

	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43.

	"d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread

	spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

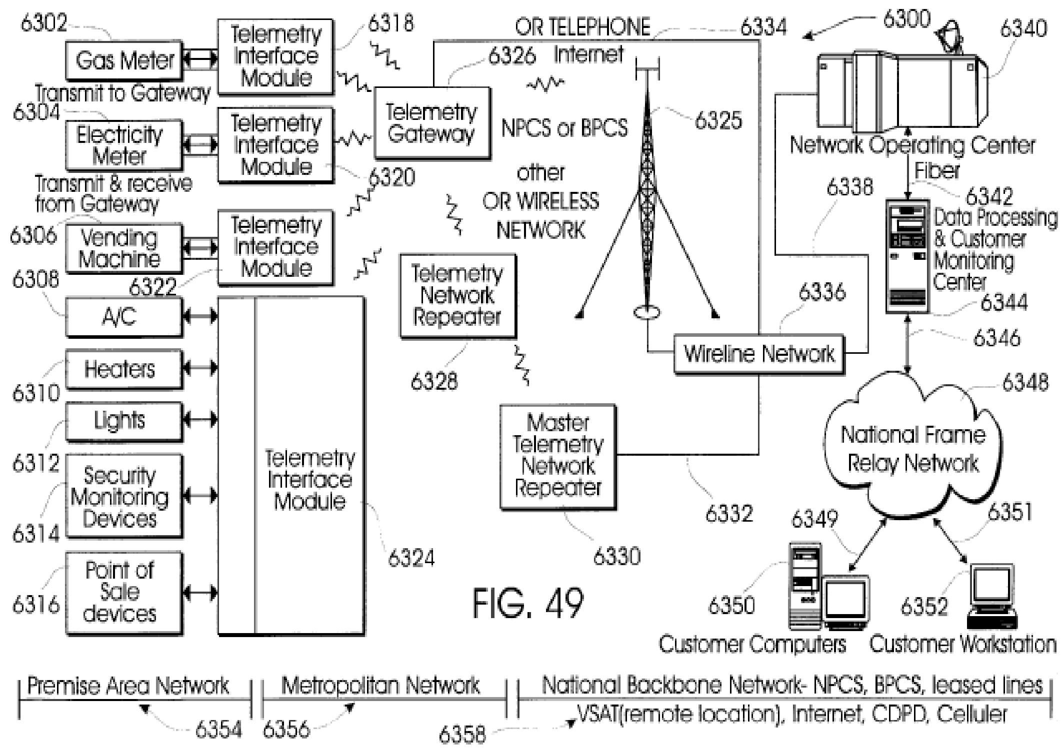

FIG. 49

To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it

	may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 55 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host

	module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49

The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	 FIG. 49 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However,

	some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for

	communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
60. A method for controlling an existing control system with a local controller comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.
adaptively configuring a data translator disposed between and in communication with both a local controller and a wireless transceiver, wherein the data translator is configured to translate the local controller data stream into an information signal consisting of a transceiver identification code and a concatenation of function codes, the data translator further configured to translate control signals from the wireless transceiver	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1.

into local controller recognized control signals;	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way

	transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	"Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110

	through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

	out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. "Returning to a consideration of FIG. 1, host module 122 is in communication with the data collection modules 110 through a network system. The host module 122 is a centrally or regionally located control center or centers which is used to monitor and control all the information exchange required by the monitoring system." '217 patent, 43:53-59.
sending the control signal via the network to the gateway;	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "2. The Data Collection Module a.. Overview The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for a RF signal modulated with a particular format. Once a valid signal is identified, the receiver stops hopping and decodes the entire data packet which is passes along CPU module for collection and evaluation." '217 patent, 18:45-55. "The data collection module 110 is a local, intelligent, data concentrator residing at

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	or near the location of the sensor interface modules 102. The data collection module 110 act as the focal point of all the information that is collected from the sensor interface modules 102 within a monitored area such as a customer's premises and transmits this information to the host module 122 over standard communication systems 118." '217 patent, 19:17-23. "Information from the sensor interface module 102 is decoded and process in the data collection module 110 and prepared for transmission to the host module 122. The processor dynamically builds a table that stores the information received from each interface module. Information is grouped by the unique identifier assigned to each individual sensor interface module." '217 patent, 31:11-17. "Returning to a consideration of FIG. 1, host module 122 is in communication with the data collection modules 110 through a network system. The host module 122 is a centrally or regionally located control center or centers which is used to monitor and control all the information exchange required by the monitoring system." '217 patent, 43:53-59. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
translating the control signal from a network transfer protocol into an RF control signal;	"The data collection module 2300 includes a housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:3-7.

	"The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time." '217 patent, 32:31-37.
transmitting the RF control signal;	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
receiving the RF control signal;	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
61. The method of claim 60, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 60 are hereby incorporated by reference. "The data collection module 2300 includes a housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:3-7.

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The

Exhibit P4– Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,366,217

	purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it

	may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference. "4. Transmitting Information to Host Module "Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

The '732 Patent – Claim	U.S. Patent No. 6,366,217
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"An effective monitoring system can be developed through the use of a sensor interface module, a data collection module, commercially available information transmission systems, and a host module. The sensor interface module will constantly monitor individual customer demand and usage to gather information for the monitoring system. The sensor interface module will send this information to the data collection module over unlicensed radio frequency bands. The data collection modules will gather information from sensor interface modules or other inputs wired directly and transmit the information to the host module over the commercially available information transmission systems." '217, 4:54-66. "Referring to the drawings in detail, FIG. 1 is a schematic representation for a wide-area remote telemetry system 100, constructed in accordance with the present invention. A plurality of sensor interface modules 102, which are electromechanical interfaces, act as data gathering equipment. Sensor interface modules 102 communicate with data collection modules 110 through a hardware or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmissions may be utilized." '217, 6:12-22. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.
	The above contentions for claim 1 are hereby incorporated by reference. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	 To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user

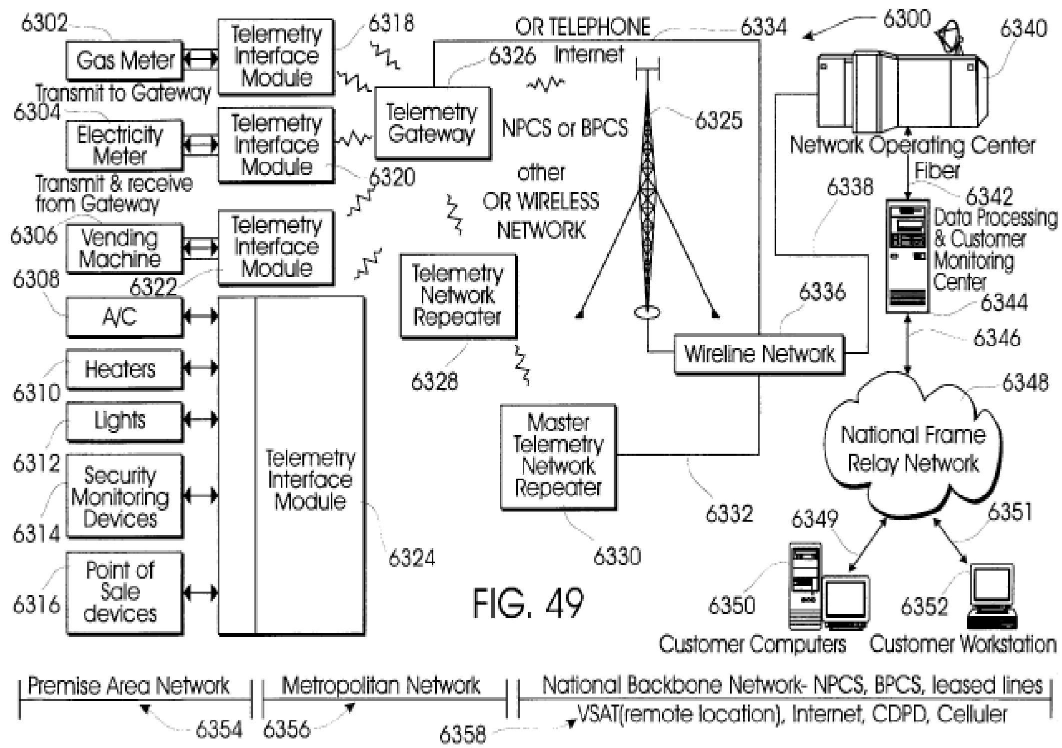
Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with	"4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

the nearby wireless transceiver, and transceiver identification information associated with one or more retransmit- ting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217



To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body

	FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7.

	"The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor,	"d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such

	special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "PMM Commands. When a RDP packet is addressed to a PMM module (odd IP address), the data is interpreted as commands." '217 patent, 37:61-64. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. 	installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
18. The device of claim 13, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the data controller can implement.	The above contentions for claim 13 are hereby incorporated by reference. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.
19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the command.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel,

	U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition

	occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive	"Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic

select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems to be monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort." '217 patent, 7:37-43. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.

wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being

	shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination

	addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31**,** further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	The above contentions for claim 31 are hereby incorporated by reference. "4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected fro the sensor interface modules 012, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32: 23-41. "IP datagrams are completely encapsulated in the data fields of RDP packets. The sequence byte allows for up to 16 packets or fragments to be transported for a single IP datagram." '217 patent, 36:36-38. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out

	on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.  FIG. 49
	The above contentions for claim 1 are hereby incorporated by reference.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	"The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

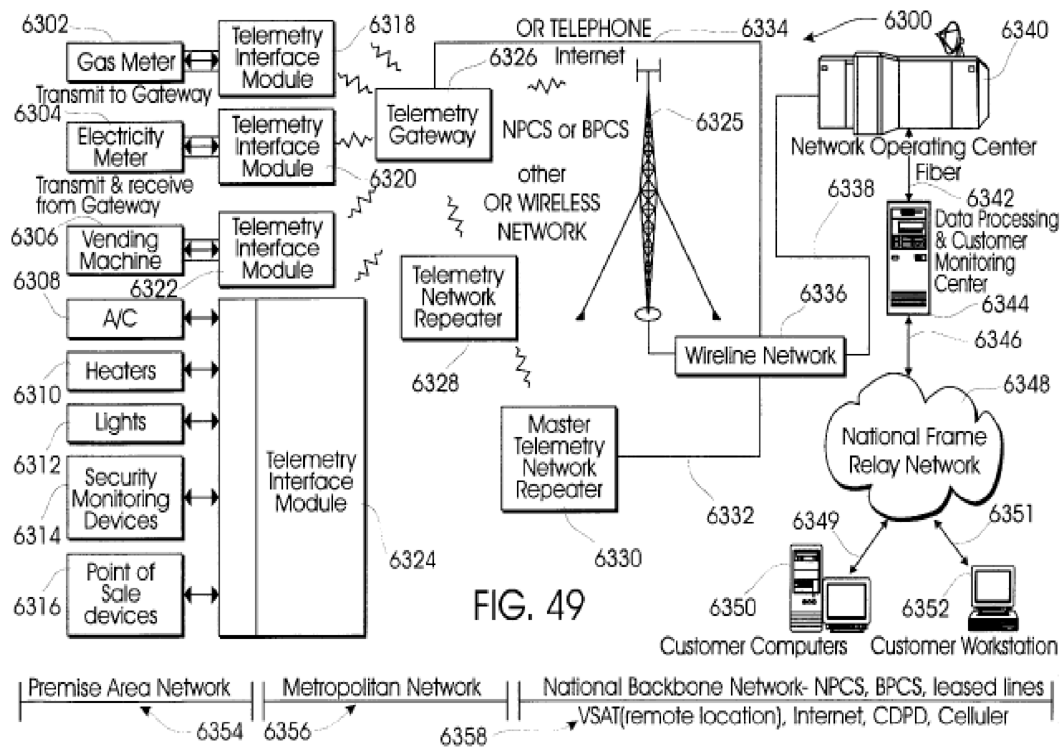

FIG. 49

To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘217 patent with the teachings of one or more of the additional references teaching this limitation, for example:

Jubin discloses:

“The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23.

	Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location

	which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the

	commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate

	wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,366,217

	invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical

	data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

The '780 Patent – Claim	U.S. Patent No. 6,366,217
1. In a system comprising a plurality of wireless devices, a device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface

	module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	"FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. '217 patent, Figure 30.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	"The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41. '217 patent, Figure 44.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

	Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through

	appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	patent, 47:1-14.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control

	module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would

	have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,366,217

	week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer

	operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the

	system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. '217 patent, Figure 1. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108. Standard wire connection may be utilized for the hardware or wireless transmission 108, or various types of known, low-power, radio-frequency transmission may be utilized." '217 patent, 6:17-22.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 6,366,217

The '842 Patent – Claim	U.S. Patent No. 6,366,217
1. A device for communicating information, the device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for an RF signal modulated with a particular format. Once the valid signal is identified, the receiver stops hopping and decodes the entire data packet which it passes along to CPU module for collection and evaluation. The receiver and the CPU modules are connected by a motherboard that also holds power regulation circuitry. … In one

	preferred embodiment, the communication module uses a MOTOROLA™ 68CH11 central processing unit, 32K of ram, 64K to 1 meg of eprom, and 144K of flash. The flow computer module uses a Rosemont™ 2055 with HART protocol signal." '217 patent, 18:45-19:1. "FIG. 25 is a block diagram of a data collection module 110. The data collection module 110 includes a radio frequency receiver 2002 to receive signals from the sensor interface module 102, a central processing unit information processor 2004 with associated firmware, a motherboard/power supply with battery backup 2006, and a transmitter/receiver 2008." '217 patent, 19:23-29. '217 patent, Figure 25.
an interface circuit for communicating with a central location; and	"The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for an RF signal modulated with a particular format. Once the valid signal is identified, the receiver stops hopping and decodes the entire data packet which it passes along to CPU module for collection and evaluation. The receiver and the CPU modules are connected by a motherboard that also holds power regulation circuitry. … In one preferred embodiment, the communication module uses a MOTOROLA™ 68CH11 central processing unit, 32K of ram, 64K to 1 meg of eprom, and 144K of flash. The flow computer module uses a Rosemont™ 2055 with HART protocol signal." '217 patent, 18:45-19:1. "Returning to a consideration of FIG. 1, the data collection module 110 provides the information transmission connection between the sensor interface module 102, and the network connection 116 to the host module 122. The data collection module 110 acts as the focal point of all the information which is collected from the sensor interface modules 102 within a monitored area such as a customer's premise and

	transmits this information to the host module 122 over standard communication systems 118." '217 patent, 19:13-23. "FIG. 25 is a block diagram of a data collection module 110. The data collection module 110 includes a radio frequency receiver 2002 to receive signals from the sensor interface module 102, a central processing unit information processor 2004 with associated firmware, a motherboard/power supply with battery backup 2006, and a transmitter/receiver 2008." '217 patent, 19:23-29. '217 patent, Figure 25. "4. Transmitting Information to Host Module Data is transmitted to the host module through the transmitter/receiver or other modem device of the data collection module 110. The data collection module 110 concentrates the data collected for the sensor interface modules 102, and uploads the information to the host module on a periodic time basis, at a preset time, or in response from a demand from the host module. … The communications between the host module and the data collection module is designed to be two-way and interactive. This allows for the data retrieval to be near real-time. …The transmission from the data collection module 110 to the host module may be by means of any number of various systems including Narrow band PCS, Broadband PCS, WPCS, CDPD, cable modems, a phone line with Internet packet data, or other information transmission systems." '217 patent, 32:23-41. "The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module. The data collection module will send and receiving information to and from the host module as an Internet protocol (TCP/IP) signal. The information signal will be sent out on the Internet, transferred across the Internet, and received by the other module." '217 patent, 46:11-16.

	 FIG. 49
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location	"The sensor interface module is programmed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection module boxes are weatherproof enclosures that house data

using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for an RF signal modulated with a particular format. Once the valid signal is identified, the receiver stops hopping and decodes the entire data packet which it passes along to CPU module for collection and evaluation. The receiver and the CPU modules are connected by a motherboard that also holds power regulation circuitry. … In one preferred embodiment, the communication module uses a MOTOROLA™ 68CH11 central processing unit, 32K of ram, 64K to 1 meg of eprom, and 144K of flash. The flow computer module uses a Rosemont™ 2055 with HART protocol signal." '217 patent, 18:45-19:1. "FIG. 25 is a block diagram of a data collection module 110. The data collection module 110 includes a radio frequency receiver 2002 to receive signals from the sensor interface module 102, a central processing unit information processor 2004 with associated firmware, a motherboard/power supply with battery backup 2006, and a transmitter/receiver 2008." '217 patent, 19:23-29. '217 patent, Figure 25.
7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The contentions for claim 1 are hereby incorporated by reference. "FIG. 21 shows the general layout of the transmitted information signal The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. '217 patent, Figure 21. "The identifier information is designed to identify the specific sensor interface module's transmission that is being received, and to identify any other type of

	information specific to the device being monitored. The information signal contains the data collected by the sensor interface module." '217 patent, 13: 62-67.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The contentions for claim 1 are hereby incorporated by reference. "The routing tables are held in the router non-volatile RAM and are used to move RDP packets from router A to router B using other router/radios if necessary. Router table entries can come from any of three sources, namely 1) a router IP command packet, 2) an external hookup with a laptop, or 3) recording the path of the received RDP packet." '217 patent, 36:60-65.
16. A device for communicating information, the device comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a processor; and	"The sensor interface module is programmed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection module boxes are weatherproof enclosures that house data collection electronics. RF input signals in the range of 902 Mhz to 928 Mhz are received through the horizontally polarized antenna and routed to the receiver module. The receiver module hops the 25 pre-set frequencies looking for an RF signal modulated with a particular format. Exhibit P4 – Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 6,366,217

	"5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
establish a communication link between at least one low-power transceiver in the network of addressable low-power transceivers and a central location based on an address included in the signal, the communication link comprising one or more low-power transceivers in the network of addressable low-power transceivers; and	"The data collection module boxes are weatherproof enclosures that house data collection electronics. "The identifier information is designed to identify the specific sensor interface module's transmission that is being received, and to identify any other type of information specific to the device being monitored. The information signal contains the data collected by the sensor interface module." '217 patent, 13: 62-67.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

The '893 Patent – Claim	U.S. Patent No. 6,366,217
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing

	unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9.

	"FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware;

	battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"After a data packet has been collected, the data will be transmitted to a data collection module or other device using Frequency Shift Keying (FSK) modulation." '217 16:6-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
a command indicator comprising a command code;	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special

	requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is

	approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number,

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically

	transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module’s assigned tier address for that network service module to be addressed.” ‘252, 42:18-39. “FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and “network message” field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. …

	Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for

	extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference. "5. Device Adjustment Modules Device adjustment modules are used to monitor and control the operation of various devices and applications according to various utility prices and the device consumption information. An example of a device control module is a module to control a Johnson Control TM thermostat by attaching a device control module with a power system, processor with associated firmware, and a radio. The module monitors the energy usage by the air conditioning and heating systems controlled by the thermostat and can adjust the operation usage to stay below increased billing increment costs for energy supply and usage. A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.

A two-way sensor interface module would be utilized. The device adjustment module transmits information to the system and receives controlling information from system update transmissions." '217 patent, 47:1-14.
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"A wide-area remote telemetry system which monitors and controls remote device by means of a information control system. The system uses a plurality of sensor interface modules which constantly monitor devices for triggering events. The sensor interface modules transmit information to at least one data collection module which gathers, process, stores and transmits information to a host system via standard external communication systems." '217 patent, Abstract.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware;

	battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "Sensor interface modules 102 communicate with data collection modules 110 through a hardwire or wireless transmission 108." '217 patent, 6:16-19. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. "The sensor interface module is programed to set the unique identifier for the device and the frequency that it transmits to the data collection module." '217 patent, 13:33-35. "The data collection modules 110 collect information from a plurality of different sensor interface modules. One-way transmission from the sensor interface module 102 to the data collection module 110 is preferred because frequent updates to the data collection module provide an adequate time resolution for potential demand reads while allowing the overall system costs to be significantly less than a two-way communication system. In addition, significant power savings can be obtained in

	the sensor interface modules 102 by utilizing a one-way transmission system between the sensor interface module 102 and data collection module 110. This one-way transmission is acceptable because the sensor interface module 102 transmits at user configurable thresholds." '217 patent, 30:60-31:5. "Other applications may require two-way transmission, such as monitoring and control of lights, security monitoring devices, utility disconnect actions, utility outage reporting, or other control functions." '217 patent, 31:6-9. "FIG. 30 shows a simplified schematic layout of data repeater module which is generally designated by the numeral 2300. The data collection 2300 includes housing 2302 which minimally contains a central processing unit 2306 and a spread spectrum receiver/radio 2308. The spread spectrum receiver/radio 2308 is used to receive or transmit signals 2320 to sensor interface modules." '217 patent, 20:1-7. "The data repeater module can perform both the functions of a standard data collection module in gathering information from sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	which transmits and receives signals." '217 patent, 33:28-41.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The sensor interface modules 102 are intelligent communications devices which attach to gas, electric, and water meters and other types of monitored equipment. The basic sensor interface modules 102 may be adapted to any number of systems being monitored, including but not limited to: electrical systems, gas systems, water systems, security systems, temperature control systems, vending machines, and remotely monitored devices of any sort. The sensor interface modules 102 include an appropriate hardware sensor for the device being monitored; a computerized monitoring system with associated firmware; battery power supply and/or converter for external power; and a transmitter." '217 patent, 7:35-48. "d. Sensor Interface Main Body FIG. 19 shows a simple block diagram layout of a sensor interface modules designated by the numeral 102. The sensor interface module 102 contains a pulse encoder 1300, central processing unit micro-controller 1302, a spread spectrum transmitter 1304 which operate together to form a transmission signal 1306. … The sensor interface module is designed to communicate with the data collection module to transmit information to be forwarded to a host module. A common RF (radio frequency) module will be incorporated with a microprocessor into a circuit board." '217 patent, 12:27-41. '217 patent, Figure 19.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"After a data packet has been collected, the data will be transmitted to a data collection module or other device using Frequency Shift Keying (FSK) modulation." '217 16:6-8.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin

	page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module,

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type.

	Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. 	September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
a command indicator comprising a command code;	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET,

	discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel

	page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

at least one data value comprising a scalable message; and	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. 	memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29.
processing the response message	
wherein all messages comprise at least one packet, the packet having a predetermined format;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
wherein the predetermined format comprises:	
a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
a sender address comprising an unique address of the sender;	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
a command indicator comprising a command code;	"Johnson '252 either uses an IDT or CDT which performs the functions of an IDT. The IDT includes a transmitter, processor, memory, and receiver. The IDT transmits a polling signal to the RCNs, receives the RCN information, transmits an acknowledgement of the receipt of the RCN information, and stores the RCN information in memory." '217 patent, 4:23-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 7,027,773 ("the '773

	patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

Exhibit P4 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,366,217

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed

	through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60. "In the preferred embodiment, the header information is approximately 65 bytes of information and the data bytes are approximately 8 bytes of information." '217 patent, 15:13-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '217 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '217 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers

	that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and

	receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network

	service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for

	Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector that is a redundancy check error detector; and	"FIG. 21 shows the general layout of the transmitted information signal. The signal consists of a header, information signal, and a CRC. The header information includes a preamble and a sensor interface module identifier." '217 patent, 13:56-60.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"The data repeater module can perform both the functions of a standard data collection module in gathering information from

	sensor interface modules, and perform the repeater functions to get the information to a connected data collection module for transmission over any number of the commercial transmission systems for data. FIG. 44 shows a schematic diagram of the overall data repeater system, called a Wireless Radio Backbone (WRB). The WRB is a wireless radio Serial Line Internet Protocol (SLIP) transport which was designed for bi-directional communication between data collection module processors. Each data collection module has a processor which talks to a router which talks to a radio which transmits and receives signals." '217 patent, 33:28-41.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

The '492 Patent – Claim	U.S. Patent No. 5,907,491
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a receiver address comprising a scalable address of at least one remote device;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. '491 patent, Figure 8. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-36. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers*

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields

	demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service

	modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. a command indicator comprising command code;	"FIG. 8 illustrates a typical preferred time-division

	communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are

	available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18

	shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine

	and/or modify the '491patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable

	fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is

	identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a controller associated with a remote device comprising a transceiver configured to send and receive wireless signals, the remote device configured to send a preformatted message comprising the receiver address, a command indicator, and the data value via the transceiver to at least one other remote device.	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. "The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:46-55. '491 patent, Figure 3.

	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. '491 patent, Figure 8.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by reference.
a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the

	status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an

	operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the

	serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
at least one sensor associated with at least one of the transceivers to detect a condition and output a data signal to the transceiver; and	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration,

	electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which

	amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.
at least one actuator associated with at least one of the transceivers to activate a device.	"In another preferred embodiment, each machine monitor in the wireless machine monitoring system includes at least one sensor which senses a parameter of the machine and produces digital data, a wireless transmitter and receiver, and a data processor for controlling the operation of the sensor, transmitter and receiver. The monitor data processor receives and processes the digital sensor data according to a first processing configuration for communicating the digital data to the transmitted and causing the transmitter to produce transmission signals corresponding to the digital data. The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration.

	A hand-held configuration device can be used for reprogramming the monitor data processor. Alternatively, reprogramming is accomplished by the command station. The configuration device includes a wireless transmitter and receiver, and a data processor for controlling and causing the transmitter to transmit configuration signals to the monitor for reprogramming of the monitor data processor and for processing wireless signals transmitted by the monitor. A user interface is also provided for inputting user commands to the configuration device data processor to control reprogramming of machine monitors." '491 patent, 3:5-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." ''491 patent, 7:56-60. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-37. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be

	programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "In another preferred embodiment, each machine monitor in the wireless machine monitoring system includes at least one sensor which senses a parameter of the machine and produces digital data, a wireless transmitter and receiver, and a data processor for controlling the operation of the sensor, transmitter and receiver. The monitor data processor receives and processes the digital sensor data according to a first processing configuration for communicating the digital data to the transmitted and causing the transmitter to produce transmission signals corresponding to the digital data. The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration. A hand-held configuration device can be used for reprogramming the monitor data processor. Alternatively, reprogramming is

	accomplished by the command station. The configuration device includes a wireless transmitter and receiver, and a data processor for controlling and causing the transmitter to transmit configuration signals to the monitor for reprogramming of the monitor data processor and for processing wireless signals transmitted by the monitor. A user interface is also provided for inputting user commands to the configuration device data processor to control reprogramming of machine monitors." '491 patent, 3:5-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." ''491 patent, 7:56-60. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-37. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through

	appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "In another preferred embodiment, each machine monitor in the wireless machine monitoring system includes at least one sensor which senses a parameter of the machine and produces digital data, a wireless transmitter and receiver, and a data processor for controlling the operation of the sensor, transmitter and receiver. The monitor data processor receives and processes the digital sensor data according to a first processing configuration for communicating the digital data to the transmitted and causing the transmitter to produce transmission signals corresponding to the digital data. The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration. A hand-held configuration device can be used for reprogramming the monitor data processor. Alternatively, reprogramming is accomplished by the command station. The configuration device includes a wireless transmitter and receiver, and a data processor for controlling and causing the

	transmitter to transmit configuration signals to the monitor for reprogramming of the monitor data processor and for processing wireless signals transmitted by the monitor. A user interface is also provided for inputting user commands to the configuration device data processor to control reprogramming of machine monitors." '491 patent, 3:5-34. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header

	corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or

	destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information

	is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59.

	'252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from	The above contentions for claim 1 are hereby incorporated by reference.

at least one other transceiver.	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This

	signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23. '491 patent, Figure 7.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
providing a receiver to receive at least one message;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station

	includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1.

	"In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which

	amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion

	when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35.

	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58.

	"The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No.

	6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header

	and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection

	bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class

	address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message

	format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space.

	Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "The basic components of the system may be configured in various ways, some of which are illustrated in FIG. 1, to meet the requirements of the particular location where the system is used. If a particular machine is located such that machine monitors 4 placed on the machine are beyond the receiving range of the command station 6, or are out of the line of sight to the command station 6, a properly located repeater 8 is used to receive the signals from the machine monitors and retransmit the signals to the command station 6." '491 patent 4:58-67.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example,

	Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets:

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31.

	"For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present,

	resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375,

	October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "In another preferred embodiment, each machine monitor in the wireless machine monitoring system includes at least one sensor which senses a parameter of the machine and produces digital data, a wireless transmitter and receiver, and a data processor for controlling the operation of the sensor, transmitter and receiver. The monitor data processor receives and processes the digital sensor data according to a first processing configuration for communicating the digital data to the transmitted and causing the transmitter to produce transmission signals corresponding to the digital data. The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration. A hand-held configuration device can be used for reprogramming the monitor data processor. Alternatively, reprogramming is accomplished by the command station. The configuration device includes a wireless transmitter and receiver, and a data processor for controlling and causing the transmitter to transmit configuration signals to the monitor for

	reprogramming of the monitor data processor and for processing wireless signals transmitted by the monitor. A user interface is also provided for inputting user commands to the configuration device data processor to control reprogramming of machine monitors." '491 patent, 3:5-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." ''491 patent, 7:56-60. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-37. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a transceiver configured to send and receive wireless communications; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for

	receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid

	necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824

	spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the

	RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. "The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial

	interface 426, and a battery status monitor circuit 428." '491 patent, 5:46-55. '491 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields).

	"The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each

	machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1.

	"In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference
	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." ''491 patent, 7:56-60. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-37. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the

	monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	status of the machine." '491 Abstract.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals

	containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "The basic components of the system may be configured in various ways, some of which are illustrated in FIG. 1, to meet the requirements of the particular location where the system is used. If a particular machine is located such that machine monitors 4 placed on the machine are beyond the receiving range of the command station 6, or are out of the line of sight to the command

	station 6, a properly located repeater 8 is used to receive the signals from the machine monitors and retransmit the signals to the command station 6." '491 patent 4:58-67. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent,

	15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.

a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable

	fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is

	identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." ''491 patent, 7:56-60. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-37. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number,

	and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message

	with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,907,491

	35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3.

21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "In another preferred embodiment, each machine monitor in the wireless machine monitoring system includes at least one sensor which senses a parameter of the machine and produces digital data, a wireless transmitter and receiver, and a data processor for controlling the operation of the sensor, transmitter and receiver. The monitor data processor receives and processes the digital sensor data according to a first processing configuration for communicating the digital data to the transmitted and causing the transmitter to produce transmission signals corresponding to the digital data. The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration. A hand-held configuration device can be used for reprogramming the monitor data processor. Alternatively, reprogramming is accomplished by the command station. The configuration device includes a wireless transmitter and receiver, and a data processor for controlling and causing the transmitter to transmit configuration signals to the monitor for reprogramming of the monitor data processor and for processing wireless signals transmitted by the monitor. A user interface is also provided for inputting user commands to the configuration

	device data processor to control reprogramming of machine monitors." '491 patent, 3:5-34. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in

	the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a transceiver configured to send and receive wireless communications; and	"The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This

	signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	"The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217

	patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

The '661 Patent – Claim	U.S. Patent No. 5,907,491
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	"In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for

	receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request

	to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9.
5. A system for monitoring remote devices, comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 patent Abstract.

at least one sensor adapted to generate an electrical signal in response to a physical condition;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which

	transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station

	includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor

	housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the

	machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage."

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an

	extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
9. A system for controlling a remote device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.

a target remote device having an actuator to be controlled;	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn,

	page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

computer integrated with a wide area network (WAN);	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and

	information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each

	machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.

	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as

	cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently

	preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which

first wireless transceiver.	transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.
12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41.

'491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique

Exhibit P5 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,907,491

	identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage."
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the	The above contentions for claim 12 are hereby incorporated by reference.

transmitter identification, and the transceiver identification information into TCP/IP for communication over the WAN.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 3. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 4. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

	‘773 patent, Figure 2. The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1.” ‘817 patent, 6:1-8.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

The '692 Patent – Claim	U.S. Patent No. 5,907,491
1. A system for remote data collection, assembly, and storage comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48.

	"In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor

	operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine….” ‘491 patent, 2:27-35. “The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary.” ‘491 patent, 4:41-57. ‘491 patent, Figure 1. “In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine.” ‘491 patent, 5:13-18. ‘491 patent, Figure 3.

	"During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code

	to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor

	operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine….” ‘491 patent, 2:27-35. “The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary.” ‘491 patent, 4:41-57. ‘491 patent, Figure 1. “In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine.” ‘491 patent, 5:13-18. ‘491 patent, Figure 3.

	"During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code

	to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as

	vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency

	(RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.

	'491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.

	"The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more

	machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more

	monitors 4." '491 patent, 7:56-58. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), …." '491 patent, 12:31-34. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by

	the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18: 8-23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43.

	"Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at

	preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.

	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the

	machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9. '491 patent, Figure 8.
12. The system as defined in claim 1, wherein the	The above contentions for claim 1 are hereby incorporated by reference.

gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

	'773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into

	the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed

	over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
14. The system as defined in claim 1, wherein the WAN is a dedicated Intranet.	The above contentions for claim 1 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses:

	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with

	the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
24. A method for controlling a system comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
remotely collecting data from at least one sensor;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor

	operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3.

	"During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code

	to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
processing the data into a radio-frequency (RF) signal;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave

	(CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.
transmitting the RF signal, via a relatively low-power transceiver, to a gateway;	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.
translating the data in the RF signal into a network transfer protocol;	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
sending the translated data to a computer, wherein	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The

the computer is configured to appropriately respond to the data generated by the at least one sensor by generating an appropriate control signal;	RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by

	changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '481 patent, 8:6-15.
sending the control signal via the network to the gateway,	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '481 patent, 8:6-15. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
translating the control signal from a network transfer protocol into an RF control signal;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor

	incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract.
transmitting the RF control signal;	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling. For example, if a particular machine is suspected of having an anomalous condition, it might be useful to instruct that machine's monitors 4 to begin collecting sand storing specific types of data for specific types of analysis, such as vibration time waveform data for zoom processing. The monitor computer 418 can also be programmed or otherwise requested to perform the zoom processing itself and store only the results of the zoom processing for later transmission to the command station." '491 patent, 7:56-8:2.
receiving the RF control signal;	"The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station

	computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
translating the received RF control signal into an analog signal; and	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
applying the analog signal to an actuator to effect the desired system response.	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform

	special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
25. The method of claim 24, wherein the RF signal contains a concatenation of information comprising encoded data information and transmitter identification information from an originating transmitter.	The above contentions for claim 24 are hereby incorporated by reference. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The

	identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
26. The method of claim 25, wherein the step of transmitting the RF signal is further performed by at least one transceiver, wherein the transceiver is configured to concatenate a transceiver identification code to the RF signal.	The above contentions for claim 25 are hereby incorporated by reference. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital

	format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
27. The method of claim 25, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 25 are hereby incorporated by reference. "The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.
28. The method of claim 25, wherein the steps of translating and applying the received RF control signal are performed only by an identified transceiver electrically integrated with an actuator.	The above contentions for claim 25 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the

	monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 25 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112.

	However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
30. The method of claim 25, wherein the network is an Intranet.	The above contentions for claim 25 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249.

	Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses:

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
31. The method of claim 25, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 25 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses:

	"When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors

	110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers.” ‘650 patent, 8:42-44. “For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112.” ‘650 patent, 10:54-57. The ‘773 patent discloses: “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. ‘773 patent, Figure 2. The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1.” ‘817 patent, 6:1-8.

32. A system for monitoring remote devices comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35.

	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34.

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor

	data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a low-power radio-frequency (RF) signal;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.
at least one gateway connected a wide area network	"The command station 6 can be connected to a PC network 10 as shown in

(WAN) configured to receive and translate the RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the

	monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information,

	and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1.

	"In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the

	form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	The above contentions for claim 32 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this

	limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses:

	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses:

	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. …

	2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. 	6:1-8.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the

	monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of

	a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine

	monitors 4." "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform

further configured to translate the analog output signal into a response.	special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. 43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The

receives and repeats the RF signal.	identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.

	The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1.” ‘817 patent, 6:1-8.
47. The system defined in claim 42, wherein the WAN is the Internet.	The above contentions for claim 42 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23. Burchfiel discloses: “When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into

	the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. 	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
49. A system for managing an arrangement of application specific remote devices comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a computer configured to execute a multiplicity of computer programs, each computer program executed to generate at least one control signal in response to at least one application system input, said computer integrated with a wide area network (WAN);	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
at least one gateway connected to the WAN configured as a two-way communication device to receive and translate the at least one control signal and the at least one application system input; said gateway further configured to translate and transmit a radio-frequency (RF) signal containing the control signal and destination information, said gateway further configured to receive and translate the at least one application system input and source information;	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '491 patent, 8:6-15.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

	'773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
at least one wireless relatively low-power RF transceiver per computer program configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator and a sensor;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-

	35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions

	for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF

	sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time

	slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response; and	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61.

	"Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
a sensor configured to translate a physical condition into an analog version of the application system input.	"Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.

	'491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.

	"The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.

	The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the

	destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers.” ‘650 patent, 8:42-44.

	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
54. The system as defined in claim 49, wherein the at least one gateway is connected to the WAN by a network selected from the group consisting of a telecommunications network, private radio-frequency network, and a computer network.	The above contentions for claim 49 are hereby incorporated by reference. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
55. A method of collecting information and providing data services comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52.

	"As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.
adaptively configuring at least one transmitter with the data translator, wherein the transmitter converts the information signal into a low-power RF signal;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.

placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,907,491

	monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data

	reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a

	similar fashion when relaying data from the command station 6 to the machine monitors 4." "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.
granting client access to the computer.	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '481 patent, 8:6-15.

56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 55 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." 	The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
60. A method for controlling an existing control system with a local controller comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
adaptively configuring a data translator disposed between and in communication with both a local controller and a wireless transceiver, wherein the data translator is configured to translate the local controller data stream into an information signal consisting of a transceiver identification code and a concatenation of function codes, the data translator further configured to translate control signals from the wireless transceiver into local controller recognized control signals;	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when

	site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the

	antenna 406." '491 patent, 15:6-15. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	"Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an

	operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an

	RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."

processing the data into an RF signal;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.
transmitting the RF signal to a gateway;	"The sensor signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistorcapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by and analog-to-digital converter 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as a Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:37-52.

	"As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.
translating the data in the RF signal into a network transfer protocol;	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by at least one sensor by generating an appropriate control signal;	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4. The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converter circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.

	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '481 patent, 8:6-15.
sending the control signal via the network to the gateway;	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage. The PC network 10 also enables an operator to reformat the time slice schedule 18 of FIG. 9. For example, the time slice schedule 18 can be reformatted by changing the order of devices within the schedule 18, changing the length of time allotted to individual slices, and changing the frequency at which status polls will be conducted." '481 patent, 8:6-15. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established

	communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
translating the control signal from a network transfer protocol into an RF control signal;	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or

	more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
61. The method of claim 60, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 60 are hereby incorporated by reference. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication

	between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003,

	which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.
62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116.

	Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

	'773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
64. The method of claim 60, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 60 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an

	extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

The '732 Patent – Claim	U.S. Patent No. 5,907,491
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

	"In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4, 31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol

	congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to

	implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained

predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57.

	'491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.

	"The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9.

with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control

	process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control."

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

	'817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication

	protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is

	integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.

	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

	similar fashion when relaying data from the command station 6 to the machine monitors 4."
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The sensor data signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistocapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by an analog-to-digital converted 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:36-52. '491 patent, Figure 3.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control

	process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control."

	'817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
17. The device of claim 13**,** wherein the data controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code	The above contentions for claim 13 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
18. The device of claim 13, further comprising a memory to store one or more function codes corresponding to the device, the function codes	The above contentions for claim 13 are hereby incorporated by reference. "In addition to those functions performed according to the communication

corresponding to a number of functions the data controller can implement.	protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "The sensor data signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistocapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by an analog-to-digital converted 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:36-55. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.
19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the	The above contentions for claim 13 are hereby incorporated by reference. "In addition to those functions performed according to the communication

command.	protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,907,491

comprising:	command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as

	vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency

	(RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the

	repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4."
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"The sensor data signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistocapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by an analog-to-digital converted 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers." '491 patent, 5:36-52. '491 patent, Figure 3.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31**,** further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	The above contentions for claim 31 are hereby incorporated by reference. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station 6 is able to transfer data and information directly to the PC network for analysis and archival storage." '491 patent, 8:6-9. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116.

	Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
33. The wireless communication system of claim	The above contentions for claim 31 are hereby incorporated by reference.

31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	"In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn,

	page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: “The “function fields” provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process.” Burchfiel page 247. “A level-3 debugging protocol has been defined which supports debugging of remote PRU’s from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting “mousetraps” which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure.” Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: “Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices.” ‘650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: “In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control.” ‘817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: “Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements.” ‘903, 4:23-31.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in	The above contentions for claim 31 are hereby incorporated by reference. “In addition to those functions performed according to the communication

response to data sensed by the sensor.	protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to	The above contentions for claim 31 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform

the sensor.	special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "The sensor data signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistocapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by an analog-to-digital converted 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:36-55. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,907,491

The '780 Patent – Claim	U.S. Patent No. 5,907,491
1. In a system comprising a plurality of wireless devices, a device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned

	to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is

	accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding

	messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,907,491

the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is

	accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. "The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:46-55. '491 patent, Figure 3.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4

	milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging."

	Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device

	and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51.

	"Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,907,491

	or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-

	35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a

	status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor

	transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host

	computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "The sensor data signals are amplified by an amplifier 412, such as a digitally controlled variable gain amplifier incorporating a chip of type number LM6684. The sensor signals are filtered to

	eliminate aliasing by means of an anti-aliasing filter 414, such as a simple resistocapacitor (RC) low-pass filter or a two-pole Sallen-Key active filter, and are then converted into digital format by an analog-to-digital converted 416, such as a 16-bit Sigma-Delta converter of type number CS5330. The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:36-55. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol. A characteristic of the machine being monitored is sensed in accordance with the communication protocol, producing sensor signals." '491 patent, 3:38-43.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,907,491

	"Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol. The method includes the steps of defining a time-division schedule of events to occur during a periodic polling sequence. Schedule events include transmitting wireless command signals from a command station to other communication devices including machine monitors, receiving wireless command signals by the machine monitors, sensing one or more characteristics of the machine to produce sensor signals, and transmitting wireless status signals to the command station. Each device is assigned a time slice within the time-division schedule during which the device powers up to receive and execute commands communicated by the command signals." '491 patent, 3:46-61. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated.” Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: “The “function fields” provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process.” Burchfiel page 247. “A level-3 debugging protocol has been defined which supports debugging of remote PRU’s from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting “mousetraps”

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 5,907,491

The '842 Patent – Claim	U.S. Patent No. 5,907,491
1. A device for communicating information, the device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41.

	"Another preferred method provides for periodically polling a plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4:31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a

	serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
an interface circuit for communicating with a central location; and	"The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of	"The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to

addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base

	for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The contentions for claim 1 are hereby incorporated by reference. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. "Each device receives its own status poll message from the command station 6. Sensors, such as tachometers 5a-c respond immediately to the status poll message, typically in less than 4 milliseconds." '491 patent, 8:32-36. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), …." '491 patent, 12:31-33. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.

9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The contentions for claim 1 are hereby incorporated by reference. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63.
16. A device for communicating information, the device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 5,907,491

	more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a processor; and	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
a memory, the memory comprising logical instructions that when executed by the processor are configured to cause the device to:	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a

	personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
wirelessly transmit a signal comprising instruction data for delivery to a network of addressable low-power transceivers;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
establish a communication link between at least one low-power transceiver in the network of addressable low-power transceivers and a central location based on an address included in the signal, the communication link comprising one or more low-power transceivers in the network of addressable low-power transceivers; and	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 5,907,491

	"A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
receive one or more low-power RF signals and communicate information contained within the signals to the central location along with a unique transceiver identification number over the communication link.	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.

17. A device for communicating information, the device comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a low-power transceiver that is configured to wirelessly receive a signal including an instruction data from a remote device;	"A command station, which includes a transceiver, is also provided to transmit wireless command signals and to receive status data through the wireless status signals." '491 patent, 2:37-39. "In addition to those functions performed according to the communication protocol, monitors may be requested by the command station to perform special data sensing, analysis, and transmission functions." '491 patent, 2:47-51. "The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "Wireless command signals are transmitted from a command station to the monitors according to the communication protocol." '491. 3:38-41. "Another preferred method provides for periodically polling a

	plurality of machine monitors for machine status data in accordance with an established communication protocol." '491 patent, 3:46-48. "In accordance with a preferred embodiment of the present invention, a block diagram of a wireless monitoring system is shown in FIG. 1. … The basic components of the system include: (1) one of more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine … (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by the operator…." '491 patent, 4:31-53. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or

	equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
an interface circuit for communicating with a central location;	"The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64. '491 patent, Figure 4.
a controller coupled to the interface circuit and to the low-power transceiver, the controller being configured to establish a communication link between the remote device and the central location using address-indicative data included in the signal;	"The command station includes a receiver and associated circuitry for producing received digital data, and a data processor for controlling and causing the receiver and associated circuitry to receive a transmission signal and produce received digital data corresponding to the transmission signal." '491 patent, 3:13-18.

	"The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "A block diagram of the command station 6 of FIG. 1 is shown in FIG. 4 The RF signal transmitted from the machine monitor 4 is received by an antenna 602 at the command station 6. A transceiver 604, which includes an RF power amplifier/down-converted circuit 606 and a modulator/demodulator circuit 608, such as those previously discussed in the description of the machine monitor 4, downconverts and demodulates the RF signal to recover the digital sensor data. The sensor data is fed over a serial interface 610 to a command station computer 612, such as a personal computer incorporating a Pentium processor or equivalent, where the information is preferably monitored in real-time for machine fault conditions and is entered into a data base for off-line trend analysis." '491 patent, 15:51-64.

	'491 patent, Figure 4.
the controller further configured to receive one or more data signals from the central location via the interface circuit and communicate information contained within the signals to the remote device.	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract. "The command station 6 can be connected to a PC network 10 as shown in FIG. 8. When so connected, the command station is able to transfer data and information directly to the PC network 10 for analysis and archival storage." '491 patent, 8:6-9 and FIG. 8.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,907,491

The '893 Patent – Claim	U.S. Patent No. 5,907,491
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor

	includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is

	fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to

	the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.

a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. "The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:46-55. '491 patent, Figure 3.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54.

a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. '491 patent, Figure 8. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.

	"During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-36. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device.

	It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A

	tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are

	programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
a command indicator comprising a command code;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "Special requests for data sensing, data analysis, data

	transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S.

	Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports

	debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice

	schedule 18. ‘491 patent, 7:25-38. “During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity.” To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *“A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header

	and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network

	digital data corresponding to the transmission signal. The system also includes means for reprogramming the monitor data processor to change the programmed processing configuration, enabling reconfiguration of the machine monitor so that data is processed according to a second process configuration." '491 patent, 3:5-23.
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine." '491 Abstract.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"A wireless machine monitoring and communication system includes one or more machine monitors which attach to one or more machines to sense a physical characteristic of the machine, such as vibration or temperature, and to produce wireless transmissions corresponding to the sensed characteristic. A command station executes machine status polling in accordance with a time-division communication protocol and processes machine status data obtained during polling to determine the status of the machine. The machine monitor incorporates a wireless transmitter for transmitting at least status information, and the command station incorporates a wireless receiver for receiving monitor transmissions. To conserve power, the machine monitors are turned on only at preprogrammed times in accordance with the time-division communication protocol. Each machine monitor includes a receiver and the command station

	includes a transmitter to enable the command station to send commands to each machine monitor." '491 patent, Abstract. "The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1.

	"In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. '491 patent, Figure 3. "During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably, the status request transmitted by the command station 6 will include instructions for which data and which functions the monitor 41 is to perform." '491 patent, 7:28-34. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4." '491 patent, 7:56-58. "As shown in FIG. 3, a preferred embodiment incorporates a radio frequency (RF) transceiver 430 which performs data transmission as well as data reception. The transceiver 430 of this preferred embodiment further consists of a modulator/demodulator circuit 432, such as the Harris HSP 3824 spread spectrum processor, which, in the transmit mode, modulates a carrier wave (CW) signal with the baseband digital sensor data. The CW signal is fed to an RF power amplifier circuit 434, such as the Hewlett Packard HPMX3003, which

	amplifies the CW signal into an RF signal to be transmitted from the antenna 406." '491 patent, 15:6-15. "The transceiver 430 also provides for receiving and decoding messages from the command station 6 which are transmitted to the machine monitor 4 in the form of RF signals." '491 patent, 15:16-19. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet. … The identification code transmitted by the machine monitor 4 is received by the command station 6, and the command station computer 612 compares the code to values stored in a table within the command station computer 612." '491 patent, 16:50-63. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion

	when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The system includes a plurality of machine monitors positioned to monitor operational characteristics of a machine. Each monitor includes a receiver for receiving wireless command signals, at least one sensor for sensing a characteristic of a machine, a data processor for receiving and processing sensor signals to produce status data, a transmitter for transmitting wireless status signals corresponding to the status of the machine…." '491 patent, 2:27-35. "In FIG. 3, a functional block diagram of the machine monitor 4 of FIG. 1 is shown. Each machine monitor 4 contains at least one sensor 408 which is integrated with the machine monitor housing in such a manner that the desired machine characteristic is accurately measured when the machine monitor housing is fastened to the machine." '491 patent, 5:13-18. "The digital sensor signals are fed to a monitor computer 418, such as the Toshiba TMP93CM41 microcomputer. …The monitor computer 418 includes a data processor 420 which performs 16-bit operations with 32-bit extended registers. The monitor computer 418 also incorporates memory 422 consisting of at least 32 kilobytes of static RAM, a timer 424, a serial interface 426, and a battery status monitor circuit 428." '491 patent, 5:46-55. '491 patent, Figure 3.
a receiver address comprising a scalable address of the at least	"FIG. 8 illustrates a typical preferred time-division

one of the intended receiving transceivers;	communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. '491 patent, Figure 8. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date),

	and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-36. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-

	B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first,

	broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a

	network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing

	explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38.

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,907,491

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
a command indicator comprising a command code;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special

	requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the

	'903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and

	depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. "During normal communications, the monitor 4 powers up once

	every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. an error detector comprising a redundancy check error detector;	"A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages; and	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41

	responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. '491 patent, Figure 8.
wherein at least one of the plurality of transceivers further sends preformatted emergency messages.	"The monitor computer 418 is programed to transmit this battery status message to the command station 6 as status data, and to transmit a battery status alert when the battery voltage falls below a programmed threshold level." '491 patent, 6:5-9. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.

	While it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.

18. The system of claim 17, wherein the controller maintains periods of silence by not sending the preformatted command messages during predetermined time periods; and	The above contentions for claim 17 are hereby incorporated by reference. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-36. "A timer 818 provides the clock signals necessary for proper timing of the receive and transmit intervals for each machine monitor 4 assigned to the repeater 8." '491 patent, 18:22-25. "While it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. 	to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. '491 patent, Figure 8.
wherein all messages comprise at least one packet, the packet having a predetermined format;	"To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54.
wherein the predetermined format comprises:	
a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. '491 patent, Figure 8. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,907,491

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20. "During the setup/configuration process, the monitor 4 receives a unique monitor 4 ID number (address), a date/time synchronization by the command station 6 (current time/date), and a date/time of a monitor's first status poll. At the date/time of the first status poll, the monitor 4 will turn on its transceiver and wait to receive a status poll command." '491 patent, 12:31-36. "To enable the command station 6 to verify which machine monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers*

	Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields

	demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,907,491

	modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse

	poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

a sender address comprising an unique address of the sender;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." '491 patent, 13:8-20.
a command indicator comprising a command code;	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18

	shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41 responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. '491 patent, 7:25-38. "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." "To enable the command station 6 to verify which machine

	monitor 4 is transmitting a data message, each machine monitor 4 transmits a unique identification code prior to the sensor data message. The identification code combined with the sensor data message comprise a data packet." '491 patent, 16:50-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message

	with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	"FIG. 8 illustrates a typical preferred time-division communication protocol for the system of FIG. 1 (excluding tachometers 5a-c) in accordance with the time slice schedule 18 shown in FIG. 9. During the first time slice 22, the command station 6 transmits a status request to monitor 41, and monitor 41

	responds by transmitting the requested status information to the command station 6 during time slice 24. Preferably the status request transmitted by the command station will include instructions for which data and which functions the monitor 41 is to perform. Alternatively, the desired data and functions are programmed into the monitor 41 and the status request is simply a request for the monitor to perform functions and transmit data in accordance with its programming. … The quantity of the data transmitted (i.e., vibration, temperature, spectral, or other) by the monitor 41 during status polling is preferably kept to a minimum to reduce the length of time required to complete the time slice schedule 18. '491 patent, 7:25-38. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '491 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '491 patent with the teachings of one or more of the additional references teaching this limitation, for example,

	Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. an error detector that is a redundancy check error detector; and	"A preferred embodiment of the invention provides for error detection in the data that the command station receives from the machine monitor 4. In accordance with a preferred error detection scheme, the machine monitor 4 transmits a 16-bit cyclic redundancy check (CRC) message immediately after transmitting the sensor data message." '491 patent, 16:25-30.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"The basic components of the system include: (1) one or more machine monitors 4 which are placed in various locations on, or in, one or more machines and which transmit wireless signals containing status data representative of the status of the machine and the status of the monitor, the machine status data being representative of machine characteristics such as vibration, electromagnetic energy, and temperature, the monitor status data being representative of monitor characteristics such as the condition of the monitor's battery, circuitry, and sensors; (2) a command station 6 which transmits commands and information to the machine monitors 4, receives data transmitted from the machine monitors 4, and formats the data as desired by an operator; and (3) one or more repeaters 8 as needed to facilitate communication between the machine monitors 4 and the command station 6, especially when site conditions make such aid necessary." '491 patent, 4:41-57. '491 patent, Figure 1. "The repeater 8 of FIG. 1 as shown in block diagram form in FIG. 7. The RF sensor data message from a machine monitor 4 is received by the antenna 802, converted down to IF by the down-

Exhibit P5 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,907,491

	converter circuit 804, and demodulated by the modulator/demodulator circuit 806 to recover the original baseband sensor data. The sensor data is then passed over the serial interface 810 of the repeater computer 812 to the data processor 814. The sensor data is the either stored in memory 816 or is passed to the modulator/demodulator circuit 806 and the RF power amplifier/down-converted circuit 804 of the repeater transceiver 808 to create a "new" RF sensor data signal. This signal is transmitted from the repeater antenna 802 to the command station 6. The repeater 8 operates in a similar fashion when relaying data from the command station 6 to the machine monitors 4." '491 patent, 18:8-23. '491 patent, Figure 7.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

The '492 Patent – Claim	U.S. Patent No. 5,963,650
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a receiver address comprising a scalable address of at least one remote device;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

	'650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically

	transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and

	an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a command indicator comprising command code;	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106). '650 patent, 6:31-41. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may

	be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to

	work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter

	memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its

	most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.

	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device.

	It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. '650 patent, 6:31-41. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.

	ETE Header: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
at least one sensor associated with at least one of the transceivers to detect a condition and output a data signal to the transceiver; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside

	of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106). "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can

	be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
at least one actuator associated with at least one of the transceivers to activate a device.	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106).

	'650 patent, 6:31-41. "In the preferred embodiment, microcontroller 214 is a low power device which monitors RF transceiver 210 for valid radio transmissions. When a radio transmission is detected, microcontroller 214 activates microprocessor 212 so that the RF transmission can be properly processed." '650 patent, 8:1-6. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106). ‘650 patent, 6:31-41. “Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer the meter data from all of the meters to its primary cache 202.” ‘650 patent, 10:7-12.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. “Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer the meter data from all of the meters to its primary cache 202.” ‘650 patent, 10:7-12. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘650 patent with the teachings of one or more of the additional references teaching this limitation, for example,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31.

	"For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present,

	resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375,

	October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from at least one other transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
providing a receiver to receive at least one message;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	'650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data

	collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more

	of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean,

	structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device

	and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service

	modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine

	and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is

	identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. 11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4. "In the preferred embodiment, microcontroller 214 is a low power device which monitors RF transceiver 210 for valid radio transmissions. When a radio transmission is detected, microcontroller 214 activates microprocessor 212 so that the RF transmission can be properly processed." '650 patent, 8:1-6. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
13. The method of claim 8, further comprising determining if an	The above contention for claim 8 is hereby incorporated by

error exists in a packet of the at least one message.	reference. "A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment, the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14.use pincodes 404, 408 to encrypt the cyclic redundancy check.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	"In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multipoint communications. In addition, source routing of messages in included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102. " '650 patent, 7:29-35. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET,

	discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the

	command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition

	to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The

	detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference.

	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106). In the preferred embodiment, RF links 114 are used to transfer data between DAs 102 and DACs 106." '650 patent, 6:31-41. "In the preferred embodiment, microcontroller 214 is a low power device which monitors RF transceiver 210 for valid radio transmissions. When a radio transmission is detected,

	microcontroller 214 activates microprocessor 212 so that the RF transmission can be properly processed." '650 patent, 8:1-6. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "Once a request for data is received, the processor 104 examines the secondary cache 108 to determine if the data is present. If it is, then the data is returned to the APP 112 without having to access the DA 102. This provides fast query response to the APP 112 and eliminates data traffic to the DA 102 entirely. If the requested data is not in the secondary cache 108, then the processor 104 initiates communication with a particular DA 102 via data acquisition device connector 106 (hereinafter DAC 106).

	'650 patent, 6:31-41. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214,

	and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multipoint communications. In addition, source routing of messages in included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102. " '650 patent, 7:29-35. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

messages for communication;	The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The

	data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." 	irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multipoint communications. In addition, source routing of messages in included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102. " '650 patent, 7:29-35. "In the preferred embodiment, microcontroller 214 is a low power device which monitors RF transceiver 210 for valid radio transmissions. When a radio transmission is detected, microcontroller 214 activates microprocessor 212 so that the RF transmission can be properly processed." '650 patent, 8:1-6. "A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment, the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can

	be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.

	Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used

	for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery

	subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4.

	'650 patent, Figure 2.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

	‘650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 (“the ‘217 patent”), U.S. Patent No. 5,907,491 (“the ‘491 patent”), U.S. Patent No. 7,027,773 (“the ‘773 patent”), U.S. Patent No. 6,100,817 (“the ‘817 patent”), U.S. Patent No. 5,874,903 (“the ‘903 patent”) or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated.” Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute

	jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent

	week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a transceiver configured to send and receive wireless	"The present invention solves the foregoing problems by

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

communications; and	providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely

	attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.

	"In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multipoint communications. In addition, source routing of messages in included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102. " '650 patent, 7:29-35. "In the preferred embodiment, microcontroller 214 is a low power device which monitors RF transceiver 210 for valid radio transmissions. When a radio transmission is detected, microcontroller 214 activates microprocessor 212 so that the RF transmission can be properly processed." '650 patent, 8:1-6. "A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment, the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

	"A.Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31.

	"For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,963,650

	resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375,

	October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

The '661 Patent – Claim	U.S. Patent No. 5,963,650
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
5. A system for monitoring remote devices, comprising:	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	"The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data

	acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the

to receive the RF signal and retransmit the RF signal;	preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvement in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-23.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2.

	"FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvement in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-23.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	data at the data collection system, substantial improvement in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-23.
9. A system for controlling a remote device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCS with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a target remote device having an actuator to be controlled;	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28.

	"A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: “The “function fields” provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process.” Burchfiel page 247. “A level-3 debugging protocol has been defined which supports debugging of remote PRU’s from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting “mousetraps” which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure.” Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: “Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling.” ‘491 patent, 7:56-60. “During normal communications, the monitor 4 powers up once every 60

	seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. "Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may

	require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. "Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	"FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59.
a plurality of non-earth orbiting transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102

Exhibit P6 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,963,650

	includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for	The above contentions for claim 12 are hereby incorporated by reference. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server

communication over the WAN.	network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvement in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-23.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

The '692 Patent – Claim	U.S. Patent No. 5,963,650
1. A system for remote data collection, assembly, and storage comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "Another feature shown by the foregoing figures is the shared hierarchical structure of the system. In particular, the DAs 102 may be shared by multiple APPs 112. … Likewise, APPs 112 may reside on a single DCS, or be distributed over a hierarchical network of computers." '650 patent, 8:33-44. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	'650 patent, Figure 3.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10.

	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Ensuring that the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1.
8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "In addition, the RF transceiver includes a modifiable program storage. The program storage allows software to be downloaded to the RF transceiver for a variety of purposes. The software can be designed to perform specific activities with the I/O device, it can be used to perform diagnostics and maintenance functions, or to provide updated functions or software release levels. A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:31-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206." '650 patent, 7:17-18. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. "The DA 102 can be programmed to periodically (e.g., once a month) read the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
12. The system as defined in claim 1, wherein the gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	The above contentions for claim 1 are hereby incorporated by reference. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP

	112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol

	congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘773 patent discloses: “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. ‘773 patent, Figure 2. The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below.

	However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." 	node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
24. A method for controlling a system comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
remotely collecting data from at least one sensor;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.
processing the data into a radio-frequency (RF) signal;	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
transmitting the RF signal, via a relatively low-power transceiver, to a gateway;	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102"). "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. " '650 patent, 5:58-6:4. '650 patent, Figure 1.
translating the data in the RF signal into a network transfer protocol;	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
sending the translated data to a computer, wherein the computer is configured to appropriately respond to the data generated by the at least one sensor by generating an appropriate control signal;	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device." '650 patent, 5:12-18. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
sending the control signal via the network to the gateway,	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device." '650 patent, 5:12-18. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
translating the control signal from a network transfer protocol into an RF control signal;	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." 	data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
25. The method of claim 24, wherein the RF signal contains a concatenation of information comprising encoded data information and transmitter identification information from an originating transmitter.	The above contentions for claim 24 are hereby incorporated by reference. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer to peer operation. For example, a user application can issue a command of query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices. This allows server workload to be greatly reduced by allowing it to offload work to the data acquisition device which would otherwise have to be performed by the server. In addition, the offload process can be dynamically altered to suit network performance requirements or to circumvent problems due to equipment malfunction." '650 patent, 5:45-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
26. The method of claim 25, wherein the step of transmitting the RF signal is further performed by at least one transceiver, wherein the transceiver is	The above contentions for claim 25 are hereby incorporated by reference. "Another advantage of the intelligent RF transceiver in the preferred

configured to concatenate a transceiver identification code to the RF signal.	embodiment is that it is capable of peer to peer operation. For example, a user application can issue a command of query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices. This allows server workload to be greatly reduced by allowing it to offload work to the data acquisition device which would otherwise have to be performed by the server. In addition, the offload process can be dynamically altered to suit network performance requirements or to circumvent problems due to equipment malfunction." '650 patent, 5:45-57. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
27. The method of claim 25, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 25 are hereby incorporated by reference. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer to peer operation. For example, a user application can issue a command of query to one data acquisition device and

	that data acquisition device can then communicate directly with other data acquisition devices. This allows server workload to be greatly reduced by allowing it to offload work to the data acquisition device which would otherwise have to be performed by the server. In addition, the offload process can be dynamically altered to suit network performance requirements or to circumvent problems due to equipment malfunction." '650 patent, 5:45-57. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
28. The method of claim 25, wherein the steps of translating and applying the received RF control signal are performed only by an identified transceiver electrically integrated with an actuator.	The above contentions for claim 25 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a

	weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1.
29. The method of claim 25, wherein the network is the Internet.	The above contentions for claim 25 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located

	anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
30. The method of claim 25, wherein the network is an Intranet.	The above contentions for claim 25 are hereby incorporated by reference. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
31. The method of claim 25, wherein the network transfer protocol is TCP/IP.	The above contentions for claim 25 are hereby incorporated by reference. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with

	the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250.

	The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
32. A system for monitoring remote devices comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants

	can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.
at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a low-power radio-frequency (RF) signal;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

at least one gateway connected a wide area network (WAN) configured to receive and translate the RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57

a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4.

	'650 patent, Figure 2. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	The above contentions for claim 32 are hereby incorporated by reference. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
38. The system defined in claim 32, wherein the WAN is a dedicated Intranet.	The above contentions for claim 32 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

	"Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249.

	Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
42. A system for controlling remote devices comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices,

	and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57 '650 patent, Figure 1.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed

	over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this

	figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28.

	"A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. "The advantage of I/O interface connector 204 is that it provides a convenient standard interface for the attachment of any number of I/O devices." '650

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	patent, 7:24-27. "The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102. As a result, the user of DA 102 is not required to have extensive knowledge of networking to implement an RF telemetry system." '650. 7:28-37.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59. '650 patent, Figure 3. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	The ‘773 patent discloses: “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. ‘773 patent, Figure 2. The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1.” ‘817 patent, 6:1-8.
49. A system for managing an arrangement of application specific remote devices comprising:	“A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA’s and stores DA data in the secondary cache.” ‘650 patent Abstract “The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line.

	Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute a multiplicity of computer programs, each computer program executed to generate at least one control signal in response to at least one application system input, said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. "Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "Another feature shown by the foregoing figures is the shared hierarchical structure of the system. In particular, the DAs 102 may be shared by multiple

	APPs 112. … Likewise, APPs 112 may reside on a single DCS, or be distributed over a hierarchical network of computers." '650 patent, 8:33-44. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59. '650 patent, Figure 3.
at least one gateway connected to the WAN configured as a two-way communication device to receive and translate the at least one control signal and the at least one application system input; said gateway further configured to translate and transmit a radio-frequency (RF) signal containing the control signal and destination information, said gateway further configured to receive and translate the at least one application system input and source information;	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Referring to FIG. 1, this figure shows an overview block diagram of the

	system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. "Ensuring that the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. '650 patent, Figure 1. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
at least one wireless relatively low-power RF transceiver per computer program configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator and a sensor;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47.

	"The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response; and	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. "The advantage of I/O interface connector 204 is that it provides a convenient
