least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	"The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '314 Patent – Claims	Leiner Reference
	approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13.

The '314 Patent – Claims	Leiner Reference
	"One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '314 Patent – Claims	Leiner Reference
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising: a client node radio modem; and a client node controller; said client node controller implementing a process including receiving and transmitting data packets via said client modem;	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED?

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '314 Patent – Claims	Leiner Reference
	Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a radio transmission path to said server node that is one of a direct link to said server node and an indirect link to said server node through at least one other client node;	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '314 Patent – Claims	Leiner Reference
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. For any type of routing method (with the exception of the most simple flooding methods), the local connectivity

The '314 Patent – Claims	Leiner Reference
	information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '314 Patent – Claims	Leiner Reference
	to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Leiner Reference
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue

The '471 Patent – Claims	Leiner Reference
	arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	information." Leiner at 13-14.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13.

The '471 Patent – Claims	Leiner Reference
	"Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in

We see this applied to packet radio in [24] and [6]." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is

The '471 Patent – Claims	Leiner Reference
	concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision

The '471 Patent – Claims	Leiner Reference
path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved

The '471 Patent – Claims	Leiner Reference
	by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The

The '471 Patent – Claims	Leiner Reference
	centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual

The '471 Patent – Claims	Leiner Reference
	network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network

The '471 Patent – Claims	Leiner Reference
	access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein the server process: receives the selected transmission path from each of the plurality of clients	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as

The '471 Patent – Claims	Leiner Reference
determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks,

While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
14. A method for providing wireless network communication comprising the steps of:	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all

The '471 Patent – Claims	Leiner Reference
a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway

The '471 Patent – Claims	Leiner Reference
	and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein said server process further comprises the step of maintaining a client link tree having client link	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
entries corresponding to an optimized transmission path for each of the plurality of clients, and	determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has

The '471 Patent – Claims	Leiner Reference
	each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact,

The '471 Patent – Claims	Leiner Reference
	is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12.

The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example,

The '471 Patent – Claims	Leiner Reference
	based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
16. A method as recited in claim 15, wherein said server process further comprises steps of:	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon

The '471 Patent – Claims	Leiner Reference
determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an

The '471 Patent – Claims	Leiner Reference
	additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example,

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination

The '471 Patent – Claims	Leiner Reference
	pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The '471 Patent – Claims	Leiner Reference
	While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	"The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable

The '471 Patent – Claims	Leiner Reference
	approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13.

The '471 Patent – Claims	Leiner Reference
	"One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	"Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
	different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '471 Patent – Claims	Leiner Reference
implementing a server process, said server process configured to:	performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
receive selected transmission paths	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two

The '471 Patent – Claims	Leiner Reference
from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes to the respective client node.	packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. The '496 Patent – Claims	Leiner Reference
	arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients; and	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	information." Leiner at 13-14.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the

The '496 Patent – Claims	Leiner Reference
	correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	"One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.

The '496 Patent – Claims	Leiner Reference
clients.	
3. A wireless network system as recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13.

The '496 Patent – Claims	Leiner Reference
	"Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the

The '496 Patent – Claims	Leiner Reference
	existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most

The '496 Patent – Claims	Leiner Reference
	dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." 	load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be

The '496 Patent – Claims	Leiner Reference
	applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways

The '496 Patent – Claims	Leiner Reference
	play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information

	applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED,

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network

The '496 Patent – Claims	Leiner Reference
	connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may

The '496 Patent – Claims	Leiner Reference
	route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission,	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means

The '496 Patent – Claims	Leiner Reference
	to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and

The '496 Patent – Claims	Leiner Reference
	forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be

The '496 Patent – Claims	Leiner Reference
between the server and the respective client.	determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be

The '496 Patent – Claims	Leiner Reference
	modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and

The '496 Patent – Claims	Leiner Reference
	congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are

The '496 Patent – Claims	Leiner Reference
	hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways,

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire

The '496 Patent – Claims	Leiner Reference
	is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12.

The '496 Patent – Claims	Leiner Reference
	"Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method

The '496 Patent – Claims	Leiner Reference
	(with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example,

The '496 Patent – Claims	Leiner Reference
	based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
19. A method as recited in claim 17, wherein said server process further comprises steps of:	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from

The '496 Patent – Claims	Leiner Reference
	the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination

The '496 Patent – Claims	Leiner Reference
	pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was

The '496 Patent – Claims	Leiner Reference
	the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	"This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem;	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition,

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said second node process of each of said second nodes includes	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is

The '496 Patent – Claims	Leiner Reference
	the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE

The '496 Patent – Claims	Leiner Reference
	PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for

The '496 Patent – Claims	Leiner Reference
	performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a link to a first node that is	"In the section above on data link control, the tradeoff between the various link

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
maintaining a second node link tree	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two

The '496 Patent – Claims	Leiner Reference
having second node link entries representing each of the plurality of second nodes;	packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point

The '496 Patent – Claims	Leiner Reference
	routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not

The '496 Patent – Claims	Leiner Reference
	needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.

The '496 Patent – Claims	Leiner Reference
	"This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. 26. The first node of claim 24, wherein	"2) Network Access-Methods and Administration: Network access means the

The '496 Patent – Claims	Leiner Reference
the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the

Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20). If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and

The '496 Patent – Claims	Leiner Reference
	then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to

Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11.

The '496 Patent – Claims	Leiner Reference
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13.

The '496 Patent – Claims	Leiner Reference
	"Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts

The '496 Patent – Claims	Leiner Reference
	are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6.

The '496 Patent – Claims	Leiner Reference
configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22), Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while

The '496 Patent – Claims	Leiner Reference
	somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. 	modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and

The '496 Patent – Claims	Leiner Reference
	congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14. "Another interesting routing structure occurs when packet radio networks are

The '496 Patent – Claims	Leiner Reference
	hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	"2) Network Access-Methods and Administration: Network access means the functional entry of a network by a person or device capable of using resources within the network or its attached devices. As a general rule it is prudent, depending upon the threat, to exercise access control at the periphery of the network rather than at some centralized (or interior) point or points. Exercising access control at some internal point means that the network must offer a petitioner transport to that point without knowledge as to whether he is entitled to entry or not. Packet radio with mobile nodes means that access can occur virtually any place within the topology. If so, how can access control best work? Most packet networks provide access through either a connected host or directly through a network-based device (such as a dial-up port). The combination is very convenient, principally for the traveling user who might find it difficult to gain access to a host when not in his normal area. Earlier conventions, wherein network access was not critically controlled and control of host access was invoked at the host only, led to considerable vulnerability to both the network and the attached hosts. Because of the wide host accessibility once network access had been gained, network-based access points have characteristically been a weak point in protecting networks from unwanted host entry. Network log-on hosts are increasingly the rule where network-based access is afforded and they may be practical depending on how close to the actual point of network entry access gets controlled. In mobile packet radio network entry can occur at any node. Mobile users may request entry (connection service) at different places at different times or different places at the same time. Obviously, it becomes more difficult to distribute

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	the access authorization in this situation than if entry were at a fixed location. If access control is decentralized, all nodes may require all authorizations for all mobile users at all times. Thus the issue is HOW SHOULD ACCESS BE CONTROLLED, AT NETWORK ENTRY OR AT SOME MORE CENTRALIZED POINT? A distributed access control system has some problems of concurrency but minimizes resource utilization in the access process. A centralized one suffers from single-point vulnerability and needs to have some means to prevent someone from tying up the network with access requests. While the above deals only with single network access it is assumed that access from the internet is also possible. Gateways may then hold the same access role as the collection of hosts, depending on how important access control to the network itself is viewed." Leiner at 17-18. It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition,

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
configured to:	as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
receive information identifying selected transmission paths from each	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be

The '496 Patent – Claims	Leiner Reference
of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and	collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their

The '496 Patent – Claims	Leiner Reference
	connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This

The '496 Patent – Claims	Leiner Reference
	can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit

The '496 Patent – Claims	Leiner Reference
	not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example, based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14. "This method is quite robust (except for errors in tables or transmissions) and, in fact, is the (new) algorithm used in the Arpanet [21] and is planned for use in the gateways of the DARPA Internet system [22], [23]. However, if the network has a relatively high rate of topology changes, the amount of traffic on the network could be very high, as every substantial topology change can produce a number of packets roughly equal to the number of nodes in the network times the number of nodes directly affected by the change. Thus this method of routing is well-suited to a network like the Arpanet or a packet radio network consisting of fixed locations where topology changes are infrequent." Leiner at 14.

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	"Another interesting routing structure occurs when packet radio networks are hierarchically organized. If the network is assumed to consist of clusters of packet radios that are interconnected, the topology between clusters is likely to change at a slower rate than that between radios, and therefore hierarchical techniques may be applicable. We see this applied to packet radio in [24] and [6]." Leiner at 14.
45. A first node for use in wireless network system including a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. There is usually no single correct choice, and the decisions are dependent on the environment that the network must work in, the requirements for performance and other functionalities, and the cost and other limitations. In addition, as new hardware and software technologies become available, the parameters governing the decisions change and often result in different selections." Leiner at 7. "1) Gateways: Gateways can perform many functions but, as far as addressing is concerned, they are packet translation devices that interpret addresses at the internet level and impose headers (addresses) appropriate both to the local networks to which they are attached as well as other networks. They are host-level devices and to work correctly must have some relationship with not only the other gateways of the internet but the network-attached hosts themselves. Gateways may have an

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"In the section above on data link control, the tradeoff between the various link parameters was discussed. In addition, there must be an interaction between network level routing algorithms (discussed below) and the control of the link parameters [20]. If link connectivity is lost, the network must determine whether it should try harder on that link (by, for example, increasing power or coding gain) or it should attempt to find a different route, thereby possibly suffering some delay and lost packets while the new route is determined." Leiner at 12. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and then take action locally that is commensurate with that global optimum. For example,

The '496 Patent – Claims	Leiner Reference
	based on the computed best total route, a node may determine which is the best node to forward the packet. At the next node, the route may be recomputed or the entire route (or portion) could be included in the packet. (The latter is considerably less robust in the face of changing topology.) This form of distributed routing can be accomplished by having each node transmit its local connectivity information explicitly to every other node. Typically a form of flooding is used to disseminate the information." Leiner at 13-14.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	"Fig. 1 shows a typical packet radio network structure [8]. A packet radio unit consists of a radio, antenna, and digital controller. The radio provides connectivity to a number of neighboring radios, but typically is not in direct connectivity with all radios in the network. Thus the controller needs to provide for store-and-forward operation, relaying packets to accomplish connectivity between the originating and destination users." Leiner at 6. "Thus there are many design choices that must be made in the development of a packet radio network. 	additional role in highly mobile networks such as packet radio where topological partitioning may occur dynamically. Under these circumstances, the gateways, normally internet devices, may take on a role of intranetwork addressing and routing. Specifically, the internet may become the trajectory over which an intranet packet gets delivered when a single network temporarily divides [22], Whenever gateways play important roles such as this in mobile packet radio networks, the following issue arises: SHOULD ADDRESSING AND ROUTING BE NETWORK- OR GATEWAY-BASED? Network-based addressing means that each network has a unique name and address of which all relevant gateways are aware. In this case, all points within a single network share some portion of their address in common. In contrast, if gateway-based addressing is used, then internet packets are routed from gateway to gateway and each gateway attached to a network must have some means to route packets to destinations within that network. Furthermore, in this case, hosts must have a means to bind themselves dynamically to at least one gateway. Gateway-based routing, while somewhat less intuitive, provides a solution to the problem of what to do when a single network becomes partitioned." Leiner at 17.
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	"Radio connectivity must be determined by the two ends of the radio link (i.e., the two packet radio units which are connected). The information from each node can be collected at a central location where connectivity is then determined, or it can be determined by the nodes themselves through a cooperative mechanism, such as exchange of the number of transmitted and received packets. In either case, a decision must be made as to the nature of the information that will be used to determine the existence of a link." Leiner at 11. "The basic job of the network management algorithms is to allow data packets to be routed through the network in an efficient and reliable manner. This entails two basic tasks. The first is the establishment of routes through the network, and the second is

Exhibit B11 – Invalidity Chart for Brownrigg Family based on Leiner Reference

The '496 Patent – Claims	Leiner Reference
	the forwarding of packets along those routes." Leiner at 12. "Because flooding techniques do not require *a priori* knowledge of the network connectivity, they are easily used for disseminating network management and control information which is used to determine that connectivity." Leiner at 13. "Point-to-point routing methods typically involve the association of a route (a sequence of links) with a source-destination pair. One method of doing point-to-point routing is to explicitly associate information in each node with a source- destination pair (connection). Typically such techniques involve a route establishment phase that occurs when the 'connection' is first recognized, and then the information stored at each node is used to perform the actual routing of the packets. Forwarding of packets then simply involves looking up the appropriate forwarding information based on the connection identifier (which is carried in the packet). If topology changes occur, a new route establishment (or re-establishment) phase would occur to assure that the correct information is stored at all the nodes in the intended route." Leiner at 13. "Thus we see that all three routing methods have a place in packet radio networks. In relatively static networks, it is often most efficient to have the nodes determine their connectivity, and then determine relatively fixed routes (which would then be modified if connectivity changed due to mobility, etc.). For more dynamic networks, where connectivity is constantly changing, higher channel efficiency can be achieved by reducing the connection setups and the associated overhead. Finally, in the most dynamic networks, where network delays preclude tracking of connectivity on any but the most local basis, flooding techniques would appear to be a reasonable approach." Leiner at 13. "HOW SHOULD THE INFORMATION THAT EACH NODE REQUIRES TO ROUTE

The '496 Patent – Claims	Leiner Reference
	PACKETS BE DISSEMINATED TO THOSE NODES? For any type of routing method (with the exception of the most simple flooding methods), the local connectivity information must be processed and made available to the nodes so that they may route the packets. Note that this is somewhat independent of the type of routing being used. However, it does depend on the method for determining link connectivity and in particular, where the resulting connectivity information resides. A popular method for doing routing in networks where functional distribution is not needed (e.g., for survivability) is to use a centralized routing server. (This, in fact, was the method used in the early DARPA packet radio network [3].) This technique has each node send its local connectivity information to a central location. At this location, routes are determined and the information required by each node to process and forward packets (such as the next node along the route) is sent to the individual network nodes on either a request basis or as a background operation which constantly updates tables in the nodes." Leiner at 13. "Use of a centralized routing server has several advantages over more distributed techniques. Because the server has all the connectivity information available (albeit not necessarily current), it can be quite efficient in the computation of routes. This can be a significant advantage in packet radio situations where both connectivity and congestion are more visible globally and where some nodes are typically collocated with mobile users as opposed to being located in some predetermined location. The centralized techniques can generally be extended to a small number of servers for load-sharing and/or backup, thus overcoming some of the problems of size and robustness inherent in a centralized method." Leiner at 13. "One method for distributing the routing process is to provide enough information to each node so that each node can simply compute for itself the best total route and

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Geier Reference
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at

The '516 Patent – Claims	Geier Reference
network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
	the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
	transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
	status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information,

The '516 Patent – Claims	Geier Reference
robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
	and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is

The '516 Patent – Claims	Geier Reference
	operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	Nodes having a gateway functions to a point-to-point network, such as the internet, would inherently involve the TCP/IP protocol. At a minimum, it would have been obvious to use TCP/IP in a point-to-point protocol network in order to provide a well-known and reliable protocol. See V. G. Cerf and R. E. Kahn, "A protocol for packet

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
	network intercommunications," IEEE Trans. Commun., vol. COM-22, pp. 637-648 (May 1974); V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978). It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of

The '516 Patent – Claims	Geier Reference
through one or more other clients of said network, and transmitting said data packet with said header; and	controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay

The '516 Patent – Claims	Geier Reference
	to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107.

The '516 Patent – Claims	Geier Reference
	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate

The '516 Patent – Claims	Geier Reference
	direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '516 Patent – Claims	Geier Reference
TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	It also would have been obvious to include a packet type to packets received by the gateway in order to provide separate processing of different kinds of packets. Such could ensure adequate quality of service for the data packet and more reliable handling of data packets of different types, which were well-known to a person of ordinary skill.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually

The '516 Patent – Claims	Geier Reference
	have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count,

	table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '314 Patent – Claims	Geier Reference
	as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '314 Patent – Claims	Geier Reference
	retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the

The '314 Patent – Claims	Geier Reference
	routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '314 Patent – Claims	Geier Reference
packet to a proper location on said second network; and a second data packet receiver configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group consisting essentially of the path to first node through the	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106.

The '314 Patent – Claims	Geier Reference
	"With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node

The '314 Patent – Claims	Geier Reference
	transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a

	table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information

The '471 Patent – Claims	Geier Reference
	as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the

current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '471 Patent – Claims	Geier Reference
authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node

The '471 Patent – Claims	Geier Reference
	N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as

The '471 Patent – Claims	Geier Reference
	before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113.

The '471 Patent – Claims	Geier Reference
	"After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	"After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the

The '471 Patent – Claims	Geier Reference
providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the

The '471 Patent – Claims	Geier Reference
	nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet.

The '471 Patent – Claims	Geier Reference
	This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away

The '471 Patent – Claims	Geier Reference
	(tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. 	entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at

The '471 Patent – Claims	Geier Reference
	a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats

The '471 Patent – Claims	Geier Reference
	the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before

The '471 Patent – Claims	Geier Reference
	transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a

The '471 Patent – Claims	Geier Reference
	status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information,

The '471 Patent – Claims	Geier Reference
	node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. 32. A wireless system as recited in claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link tree when said comparison meets predetermined conditions.	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide

The '471 Patent – Claims	Geier Reference
	just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways,

The '471 Patent – Claims	Geier Reference
	including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and maintaining a second node link tree having second node link entries at the first node.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '471 Patent – Claims	Geier Reference
	each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may

The '471 Patent – Claims	Geier Reference
	benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is

The '471 Patent – Claims	Geier Reference
	to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the

"With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	"Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108.

The '496 Patent – Claims	Geier Reference
	"On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the

The '496 Patent – Claims	Geier Reference
	table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). This ensures other nodes get the updates as soon as possible." Geier at 113.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07.

The '496 Patent – Claims	Geier Reference
	"The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or

The '496 Patent – Claims	Geier Reference
	near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
7. A wireless network system	"With packet radio networks, the distance between source and destinat.ion nodes

The '496 Patent – Claims	Geier Reference
comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network

The '496 Patent – Claims	Geier Reference
	interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away

The '496 Patent – Claims	Geier Reference
	(tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. 	addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111.

The '496 Patent – Claims	Geier Reference
	"Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106.

server selected transmission path for each of the clients to the respective clients; and maintains a client link tree having client link entries representing each of the plurality of clients.	"With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node

The '496 Patent – Claims	Geier Reference
	transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. This ensures other nodes get the updates as soon as possible." Geier at 113.
12. A method for providing wireless network communication comprising: utilizing a server implementing a	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '496 Patent – Claims	Geier Reference
	"After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at

	109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to

The '496 Patent – Claims	Geier Reference
	each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly

The '496 Patent – Claims	Geier Reference
	monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1

The '496 Patent – Claims	Geier Reference
	entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105.

The '496 Patent – Claims	Geier Reference
between the server and the respective client.	"In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has

The '496 Patent – Claims	Geier Reference
	a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the

The '496 Patent – Claims	Geier Reference
	new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109.

The '496 Patent – Claims	Geier Reference
	It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. performing node link tree housekeeping functions;	"Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes; dynamically updating the tree to	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is

The '496 Patent – Claims	Geier Reference
	causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.

The '496 Patent – Claims	Geier Reference
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	"The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the

The '496 Patent – Claims	Geier Reference
	circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
the first node comprising: a first node controller; and a first node radio modem, wherein said first	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network

The '496 Patent – Claims	Geier Reference
node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting data packets via said first node radio modem; and	routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).

The '496 Patent – Claims	Geier Reference
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done,

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both."

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106.

The '496 Patent – Claims	Geier Reference
	"With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node

The '496 Patent – Claims	Geier Reference
	transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a

The '496 Patent – Claims	Geier Reference
	response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
38. A method as recited in claim 37, wherein said first node process further includes:	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
39. A method as recited in claim 37, wherein said first node process	It would have been obvious to implement authentication of clients and maintenance of the network map, including the addition and deletion of nodes.

The '496 Patent – Claims	Geier Reference
further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process, said server process configured to:	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. 	"The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. With this information, a node can make educated decisions on which node to send outgoing packets to for delivery to a specific 1ocation. A node transmits a packet to the neighbor where packets came from with the least hop count and originated from the desired destination node." Geier at 108. "On the other hand, a network with highly mobile nodes and limited bandwidth may benefit from a backward learning technique if there are frequent data transmissions between nodes." Geier at 109. "If for some reason the network can not support a connection by way of the chosen circuit., then the algorithm will choose another circuit. based on the same routing table level as before if another destination node entry resides at that) level or drop down through the truth table to higher-numbered levels until another destination node entry is found. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111.

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	"Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	"With packet radio networks, the distance between source and destinat.ion nodes typically necessitates one or more nodes to relay data to the final destination. Thus, some form of routing must. take place. This paper explains several current network routing algorithms and shows their relevance to packet, radio networks. In addition, current research at. AFIT concerning the development of an automatic routing algorithm for Air Force Logistics Command's (AFLC) HF packet radio network is explained." Geier at 105. "Most routing algorithms store node address information in tables, which show the

Exhibit B12 – Invalidity Chart for Brownrigg Family based on

The '496 Patent – Claims	Geier Reference
	next node to receive a packet. These routing algorithms may be static or dynamic. If the algorithms are static (nonadaptive) the table entries do not change during normal operateion of the network. Dynamic (adaptive) routing algorithms periodically update the tables to reflect changes in the network's topology or utilization or both." Geier at 105. "Each node in AFLC's packet radio network consists of an Advanced Electronics Applications, Inc. PIG232 Multi-Mode Data Controller, which acts as a terminal node controller (TNC). In addition, each TNC connects to an AN/URC-119 (HF) broadcast radio that prepares the data for transmission through the atmosphere. A software interface, written at AFIT, interfaces with the TNC. The interface allows an operator at a node location to send text messages to other node sites. The TNC controls the HF radio and accepts commands from the operator via the software interface." Geier at 109. It would have been obvious for a node in the network to serve as a gateway to, e.g., the internet, so that a node could access a web server, e.g., as such was well-known in the art. Such a gateway would provide translation between the networks and appropriate formatting of packets. Various references disclose such gateways, including Kahn 1978 and V. G. Cerf and P. T. Kirstein, "Issues in packet network interconnection," Proceedings of the IEEE, Vol. 66, No. 11 (Nov. 1978).
maintaining a client link tree having client link entries representing each of the plurality of clients, and receiving information identifying the selected transmission path from each of the plurality of clients,	"The RCC calculates the best route (normally in terms of least delay) and sends each node new routing table information depending on the most recently measured state of the network." Geier at 105. "In most cases, a source node needing to send data packets can notify the RCC of the source and destination. The RCC will respond with a special call request packet called a

The '496 Patent – Claims	Geier Reference
determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients.	needle packet, that contains the route which is the most efficient circuit. The route is specified as an ordered set of nodes. The source node then sends the needle packet through the network to establish the circuit, and then data packets can follow." Geier at106. "With distributed routing, each node distributes routing metrics (connectivity information, node delays) throughout the network, enabling other nodes to update routing tables. Distributed routing has proven to be very robust with ARPANET (Advanced Research Project Agency Network). Within AR.PANET, each node periodically measures the delay to each node within one transmission hop and puts this information into a status packet. Nodes within one transmission hop are known as neighbors. The node then transmits the status packet to each neighbor, which records the status information. Each neighbor repeats the delay measuring process, formulates a status packet containing local delay information as well as delay information from incoming status packets and sends this status packet to each of its neighbors. By having all nodes follow this process, each node will eventually have an overall "picture" of the network in terms of node-to- node delays. Each of the nodes can then determine the route of least delay by referring to the status information received from other nodes." Geier at 106. "Jubin and Tornow explain that the DARPA (Defense Advanced Research Project Agency) packet radio network (not ARPANET) applies distributed routing techniques by having each node maintain a tier table [2]. The tier table specifies nodes that are one hop away (tier 1), two hops away (tier 2), three hops away (tier 3), and so on. The tier table is arranged in a matrix format. The tiers represent. the rows, whereas the tier 1 entries head off the columns. For example, node X could have a tier table as shown in Figure 1. Here, nodes A, B, and C are neighbors of node X; nodes D and E are neighbors of node A; node N and J are neighbors of node D; node F is a neighbor of node B, and so on. If node X has a packet needing transmission to node F, node X would choose to send the packet to node F via node B because the transmission would take only two hops in comparison to three hops if sent via node C. The tier table gives information regarding connectivity among the

The '496 Patent – Claims	Geier Reference
	nodes; therefore, software at the source node may use the tables to make effective routing decisions." Geier at 106-07. "The nodes update their tier tables in the following manner. Every 7.5 seconds, each node transmits a Packet. Radio Organization Packet (PROP) that announces the node's existence and includes a copy of its tier table. A node receiving a PROP simply includes the information in its own tier table. After a period of time, all nodes in the network will have complete connectivity information for the entire network." Geier at 107. "The backward learning approach assumes data packet headers contain source node addresses and hop counters. The source node initializes the hop counter to zero before transmitting the packet, and intermediate nodes increment the hop counter by one before retransmitting the packet. For the purpose of updating routing tables, each node constantly monitors the incoming packets by noting the packet's original source address, hop count, and address of the immediately preceding node. In addition, the algorithm will initiate a probing that will determine which part of the circuit is causing the original circuit to be faulty. The algorithm will accomplish the probing similar to the method technicians use to manually troubleshoot a faulty circuit. First, the resident node will fabricate and send a probe packet that is addressed to an intermediate node at or

The '496 Patent – Claims	Geier Reference
	near the center of the faulty circuit. If this node is available and still connected to the circuit., it will send an immediate response to the sender. If the resident node receives a response from the intermediate node, the resident node can assume the circuit is operational up to the that point in the circuit, and if the resident node does not4 receive a response, the resident node can assume the problem lies somewhere between the resident and the intermediate node. The resident node will continue probing in the appropriate direction until a faulty node pair is found." Geier at 111. "Routinely, a node inherently sends redundant looping information when sending a status packet. The reason for this is that the status packet contains a copy of the routing table of the sender which normally includes the receiving node's level 1 entries. This causes the looping redundancy in Figure 4(a). In fact, if nothing is done, continual status transmissions will not only cause looping in the tables, but it will make the routing tables grow in length without bound." Geier at 113. "A method to reduce the looping and endless routing table growth is to "prune" the table after using the status packet to update table entries. The objective in pruning is to delete any parts of the routing table that represent circuits with a loop through particular nodes (not only the resident node). By eliminating all circuits that cause this looping, the resulting pruned table will not grow indefinitely, and it will provide just enough redundancy to accommodate valid alternate routes." Geier at 113. "After pruning, the resident node will immediately broadcast a status packet if the new routing table structure is different than before receiving the last status packet. This ensures other nodes get the updates as soon as possible." Geier at 113.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	Reasons for Patent Ineligibility
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "gateway," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
	Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	The "map" clause is abstract. It adds a "map of data packet transmission paths of a plurality of clients," and states that a "path" can be "through one or more of other clients of said first network," which is not limiting, as it would seemingly be true of every "transmission path." Thus, the map is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The map does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a map is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	The "changes the transmission paths" clause is abstract. It adds "changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway" based on choices from a group. The limitation is abstract. It is not expressed how the transmission paths are "changed," for example. Moreover, in a network environment, controllers that "change" paths are common. Thus, the changing recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The changing the transmission paths recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, changing paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, the type of protocol used in the second network (i.e., "TCP/IP protocol") does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, TCP/IP protocol is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
	included in these responses.
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and destined for the second network into a format used by the second network.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, translation of data packets does not add "significantly more" to the abstract radio network of the claim. Further, that a gateway translates data packets between networks is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, translation of data packets and addition of headers with address and indicator information does not add "significantly more" to the abstract radio network of the claim, especially as the information is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, that a gateway translates data packets between networks is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	
10. A method providing a gateway between a wireless network and a second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "gateway," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice*

The '516 Patent – Claims	Reasons for Patent Ineligibility
data packet with said header; and	requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Moreover, translation of data packets and addition of headers with address and indicator information does not add "significantly more" to the abstract radio network of the claim, especially as the information is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, that a gateway translates data packets between networks is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients.

The '516 Patent – Claims	Reasons for Patent Ineligibility
	The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	The "changing the transmission path" clause is abstract. It adds "changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway" based on choices from a group. The limitation is abstract. It is not expressed how the transmission paths are "changed," for example. Moreover, in a network environment, "changing" paths is common. Thus, the changing recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The changing the transmission paths recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, changing paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network; wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, the type of protocol used in the second network (i.e., "TCP/IP protocol") does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, TCP/IP protocol is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	included in these responses.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, the "map" clause is abstract. It adds a "map of data packet transmission paths of a plurality of clients of the wireless network" can be "through one or more other clients of the first network," which is not limiting, as it would seemingly be true of every "transmission path." Thus, the map is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The map does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a map is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '516 Patent – Claims	Reasons for Patent Ineligibility
transmission paths to optimize the data packet transmission paths of the clients.	The "dynamically updating" clause is abstract. It adds a "dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the clients." The limitation is abstract. It is not expressed how the transmission paths are "dynamically updated," for example, and Moreover, in a network environment, "updating" paths is common. Thus, the updating recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The updating recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, it does not add any meaningful limitation to a map due to the abstract nature of "optimization." Further, updating is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	Reasons for Patent Ineligibility
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node" and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any controllers and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this

The '314 Patent – Claims	Reasons for Patent Ineligibility
	case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or through at least one of the remainder of said plurality of second nodes; and	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "direct or through" does not save the claim from abstraction because "direct or through" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '314 Patent – Claims	Reasons for Patent Ineligibility
	illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized	The "utilizes the least number of other second nodes" clause is abstract. It adds utilizing "the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized." The limitation is abstract. It is not expressed how the transmission paths are "utilized," for example. Moreover, in a network environment, shortest path utilization of paths is common. Thus, the utilization recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The utilization recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Moreover, it does not add any meaningful limitation to a selection due to the abstract nature of "optimized." Selecting a path is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	The "implements changes to upgrade the selected transmission path" clause is abstract. It adds implementing "changes to upgrade the selected transmission path in response to a request from at least one of said second nodes." The limitation is abstract. It is not expressed how the transmission paths are

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '314 Patent – Claims	Reasons for Patent Ineligibility
	"upgraded," for example, or how "a request" is made. Moreover, in a network environment, "upgrading" paths on request is common. Thus, the updating recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The upgrading recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, upgrading paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said second network; and a second data packet receiver configured to receive the data packet from said second network, a second	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node," "gateway," "and "packet receiver") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes" or "gateway." It is said to include a generic "gateway" and a generic "receivers" and "converters," but does not specify any structures that improve the gateway. Instead, the gateway simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to gateways and is nothing more than abstraction of a generic radio communication in a gateway environment.

The '314 Patent – Claims	Reasons for Patent Ineligibility
converter configured to convert the data packet to a format used in said wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any gateway. They do not recite improvements to radio communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of the use of a gateway for radio communication. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through a gateway. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic gateway communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic gateways. The core of what the claim is doing is the abstract idea of data networking using a gateway. The claim is patent ineligible under §101.
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that	The implementing "a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node" is based on choices from a group.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '314 Patent – Claims	Reasons for Patent Ineligibility
the path to the first node is chosen from the group consisting essentially of the path to first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	The limitation is abstract. It is not expressed how the transmission paths are "changed," for example. Moreover, in a network environment, "changing" paths is common. Thus, the changing recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The changing the transmission paths recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, changing paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising: a client node radio modem; and a client node controller; said client node controller implementing a process including receiving and transmitting data packets via said client modem;	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server node," "client node," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server node" or "client node." They are said to include generic "controllers" and a generic "radio modems," but do not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers

The '314 Patent – Claims	Reasons for Patent Ineligibility
	and radio communications and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any server node and any client nodes with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
selecting a radio transmission path to	The "selecting" limitation fails to recite anything more than an abstraction. The

The '314 Patent – Claims	Reasons for Patent Ineligibility
said server node that is one of a direct link to said server node and an indirect link to said server node through at least one other client node;	claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server node and an indirect link to said server node through at least one other client node" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	The "implementing a process requesting updated radio transmission path data from said server node" clause is abstract. It adds implementing "requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path." The limitation is abstract. It is not expressed how the transmission paths are "upgraded," for example, or how "a process requesting" is implemented. Moreover, in

The '314 Patent – Claims	Reasons for Patent Ineligibility
	a network environment, "upgrading" paths on request is common. Thus, the updating recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The upgrading recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, upgrading paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network; a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node," "gateway," "network interface," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "gateway" or "first node." It is said to include a generic "network interface," a generic "controller" and a generic "radio modem," but does not specify any structures that improve the interface, controller, or radio modem. Instead, the node simply communicates data in a well-known manner for a gateway. Thus, the claim language is ubiquitous to gateways, controllers, and radio communications and is nothing more than abstraction of a generic radio communication in a gateway

The '314 Patent – Claims	Reasons for Patent Ineligibility
said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any gateway nodes with any controllers and any radios making any transmissions of any data. They do not recite improvements to gateway structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication in a gateway environment. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions using a gateway. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic node communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes and gateways. The core of what the claim is doing is the abstract idea of data networking using a gateway. The claim is patent ineligible under §101.
said digital controller maintaining a map of data packet transmission	The "map" clause is abstract. It adds a "map of data packet transmission paths to a plurality of second nodes of said first network," and states that a "path" can be

The '314 Patent – Claims	Reasons for Patent Ineligibility
paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	"through one or more of other second node of said first network," which is not limiting, as it would seemingly be true of every "transmission path." Thus, the map is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The map does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a map is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein said digital controller changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through	The "changes the transmission paths" clause is abstract. It adds "changes the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node" based on choices from a group. The limitation is abstract. It is not expressed how the transmission paths are "changed," for example. Moreover, in a network environment, controllers that "change" paths are common. Thus, the changing recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The changing the transmission paths recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, changing paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '314 Patent – Claims	Reasons for Patent Ineligibility
the fastest second nodes.	
13. A first node as recited in claim 12, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller converts data packets received from the first network and destined for the second network into a format used by the second network.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, translation of data packets does not add "significantly more" to the abstract radio network of the claim. Further, that a gateway translates data packets between networks is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
14. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver implementing a process to receive a data packet from a second node of said wireless network, a first converter implementing a process to convert said data packet to a format used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node," "gateway," "and "packet receiver") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes" or "gateway." It is said to include a generic "gateway" and a generic "receivers" and "converters," but does not specify any structures that improve the gateway. Instead, the gateway simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to gateways and is nothing

The '314 Patent – Claims	Reasons for Patent Ineligibility
network; and a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any gateway. They do not recite improvements to radio communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of the use of a gateway for radio communication. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through a gateway. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic gateway communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic gateways. The core of what the claim is doing is the abstract idea of data networking using a gateway. The claim is patent ineligible under §101.
a controller implementing a process to change a transmission path to optimize a transmission path includes	The "change a transmission path" clause is abstract. It adds a controller to "change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node" based on choices from a

The '314 Patent – Claims	Reasons for Patent Ineligibility
changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	group. The limitation is abstract. It is not expressed how the transmission paths are "changed," for example. Moreover, in a network environment, controllers that "change" paths are common. Thus, the changing recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The changing the transmission paths recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, changing paths is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	Reasons for Patent Ineligibility
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "controller," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a server environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).

The '471 Patent – Claims	Reasons for Patent Ineligibility
	Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	The "initiates and selects" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server" does not save the claim from abstraction because "one of a direct link to said server and an indirect link to said server" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "corresponding to an optimized transmission path for each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "optimization." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission	The "server process" clause is abstract. It adds that the server process is configured to "receive the selected transmission path from each of the plurality of clients," to "determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," to "update the client link entries to provide the optimized transmission path," and to "send the optimized transmission path for each of the clients to the respective clients."

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "optimized" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "optimization." Moreover, in a network environment, processes that "update" a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed sending process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, creating and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined

The '471 Patent – Claims	Reasons for Patent Ineligibility
	conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
4. A wireless network system as recited in claim 3, wherein said server process further comprises:	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim.

The '471 Patent – Claims	Reasons for Patent Ineligibility
logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping functions," "clients," and "wireless communication") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the

The '471 Patent – Claims	Reasons for Patent Ineligibility
	height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "corresponding to an optimized transmission path for each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "optimization." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein the server process is configured to: receive the selected transmission path	The "server process" clause is abstract. It adds that the server process is configured to "receive the selected transmission path from each of the plurality of clients," to "determine the optimized transmission path for each of the plurality of clients based

The '471 Patent – Claims	Reasons for Patent Ineligibility
from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	on the selected transmission paths received from the plurality of clients," to "update the client link entries to provide the optimized transmission path," and to "send the optimized transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "optimized" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "optimization." Moreover, in a network environment, processes that "update" a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed sending process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, creating and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept.

The '471 Patent – Claims	Reasons for Patent Ineligibility
update said client link tree when said comparison meets predetermined conditions.	The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described

The '471 Patent – Claims	Reasons for Patent Ineligibility
	throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping functions," "clients," and "wireless communication") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication.

The '471 Patent – Claims	Reasons for Patent Ineligibility
	The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur.

The '471 Patent – Claims	Reasons for Patent Ineligibility
	The recitation that the path is "one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and	The "server process" clause is abstract. It adds that the server process "receives the selected transmission path from each of the plurality of clients," "determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," "updates the client link entries to provide the optimized transmission path," and "sends the optimized transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "optimized" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "optimization." Moreover, in a network environment, processes that "update" a network map are common, as is

The '471 Patent – Claims	Reasons for Patent Ineligibility
sends the optimized transmission path for each of the clients to the respective clients.	the notification to other nodes of an updated map, as called for in the claimed sending process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, creating and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
11. A method as recited in claim 10, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics

The '471 Patent – Claims	Reasons for Patent Ineligibility
	are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
12. A method as recited in claim 11, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic

The '471 Patent – Claims	Reasons for Patent Ineligibility
link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.

The '471 Patent – Claims	Reasons for Patent Ineligibility
14. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping step," "clients," and "data packet transmission") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in

The '471 Patent – Claims	Reasons for Patent Ineligibility
	monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection

The '471 Patent – Claims	Reasons for Patent Ineligibility
	boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "corresponding to an optimized transmission path for each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "optimization." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received	The "server process" clause is abstract. It adds that the server process "receives the selected transmission path from each of the plurality of clients," "determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," "updates the client link entries to provide the optimized transmission path," and "sends the optimized transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the

The '471 Patent – Claims	Reasons for Patent Ineligibility
from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	abstract radio network. With regard to "determining," it is not expressed how the "optimized" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "optimization." Moreover, in a network environment, processes that "update" a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed sending process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, creating and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic;	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and

The '471 Patent – Claims	Reasons for Patent Ineligibility
determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client into said client link tree if said client is authentic.	"inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny

The '471 Patent – Claims	Reasons for Patent Ineligibility
	because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node" and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any controllers and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional

The '471 Patent – Claims	Reasons for Patent Ineligibility
	activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes; and	The "initiating" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "a link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because it merely recites that the second nodes have an indirect channel of communication. Further, the "initiation" of an indirect communication path does not

The '471 Patent – Claims	Reasons for Patent Ineligibility
	add significantly more because it merely encompass typical packet radio communications, and is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	The "updating" and "modifying" clauses are abstract. It adds a process that "dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized." For example, it is not expressed how the link tree is "updated" or "modified," for example, rendering the language abstract, particularly due to the abstract nature of "optimized." Moreover, in a network environment, processes that "update" and "modify" link trees are common. Thus, the clauses are abstract in general because their characteristics are not described, and are abstract in particular because they are in no way implemented in the claim. The "updating" and "modifying" recitations do not add "significantly more" to the abstract radio network of the claim because they are not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "updating" and "modifying" link trees are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
18. A wireless network system as	The asserted dependent patent claim is patent-ineligible as a matter of law under 35

The '471 Patent – Claims	Reasons for Patent Ineligibility
recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny

The '471 Patent – Claims	Reasons for Patent Ineligibility
	because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
19. A wireless network system as recited in claim 18 wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining" and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link

The '471 Patent – Claims	Reasons for Patent Ineligibility
	tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "housekeeping functions," and "wireless radio") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the

The '471 Patent – Claims	Reasons for Patent Ineligibility
send/receive data buffer in a digital memory, and	processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients, e.g., and any wireless transmissions of any data. They do not recite improvements to node structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communications between nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same nodes. The core of what the claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
selecting a link to said first node that	The "selecting" limitation fails to recite anything more than an abstraction. The

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
the first node process further comprises maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	The "maintaining," "updating" and "rerouting" clauses are abstract. It adds a process "maintaining a second node link tree having second node link entries, dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes." For example, it is not expressed how the link tree is "maintained" or "updated" or how data packets are "rerouted," for example, rendering the language abstract.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	Moreover, in a network environment, processes that "update" and "modify" link trees and that "reroute"data packets are common. Thus, the clauses are abstract in general because their characteristics are not described, and are abstract in particular because they are in no way implemented in the claim. The "maintaining," "updating" and "rerouting" clauses do not add "significantly more" to the abstract radio network of the claim because they are not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "maintaining," "updating" and "rerouting" are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics

The '471 Patent – Claims	Reasons for Patent Ineligibility
	are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic

The '471 Patent – Claims	Reasons for Patent Ineligibility
already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.

The '471 Patent – Claims	Reasons for Patent Ineligibility
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "housekeeping functions," and "wireless radio") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients, e.g., and any wireless transmissions of any data. They do not recite improvements to node structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in

The '471 Patent – Claims	Reasons for Patent Ineligibility
	monopolization of the entire field of radio communications between nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same nodes. The core of what the claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
the first node process further comprises maintaining a second node link tree having second node link entries.	The "second node link tree" clause is abstract. It adds "maintaining a second node link tree having second node link entries," which does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
32. A wireless system as recited in claim 31, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison

The '471 Patent – Claims	Reasons for Patent Ineligibility
logic updating said second node link tree when said comparison meets predetermined conditions.	or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
33. A wireless system as recited in	The asserted dependent patent claim is patent-ineligible as a matter of law under 35

The '471 Patent – Claims	Reasons for Patent Ineligibility
claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '471 Patent – Claims	Reasons for Patent Ineligibility
	original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node" and "R.F. transmission") to communicate. With regard to the steps, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "process," but does not specify any steps that improve the node. Instead, the node simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to nodes and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with processes making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are

The '471 Patent – Claims	Reasons for Patent Ineligibility
	admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are

The '471 Patent – Claims	Reasons for Patent Ineligibility
	exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
maintaining a second node link tree having second node link entries at the first node.	The "second node link tree" clause is abstract. It adds "maintaining a second node link tree having second node link entries at the first node," which does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
35. A method as recited in claim 34, wherein said first node process	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim.

The '471 Patent – Claims	Reasons for Patent Ineligibility
further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients

The '471 Patent – Claims	Reasons for Patent Ineligibility
	communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link

The '471 Patent – Claims	Reasons for Patent Ineligibility
	tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server node," "client nodes," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server node" or "client node." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that

The '471 Patent – Claims	Reasons for Patent Ineligibility
	improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.

The '471 Patent – Claims	Reasons for Patent Ineligibility
said server process configured to: receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes to the respective client node.	The "server process" clause is abstract. It adds that the server process is configured to "receive selected transmission paths from each of the plurality of client nodes…," to "determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes," and to "send the optimized transmission path for each of the plurality of client nodes to the respective client node." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "optimized" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "optimization." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, creating and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The recitation that the path is "one of a direct link to the server node and an indirect link to said server node through at least one other client node" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites

The '471 Patent – Claims	Reasons for Patent Ineligibility
	such that every path must be one or the other. That recitation is the height of abstraction. Further, the presence of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time making it no option at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available then the recitation is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract network may be implemented.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, performing "gateway functions" does not add "significantly more" to the abstract radio network of the claim. Further, that gateway functions is abstract concept and, at most, are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	Reasons for Patent Ineligibility
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "gateway," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients; and	The "initiates and selects" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server" does not save the claim from abstraction because "one of a direct link to said server and an indirect link to said server" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and maintain a client link tree having client link entries representing each of the plurality of clients.	The "server process" clause is abstract. It adds that the server process is configured to "receive information identifying the selected transmission path from each of the plurality of clients," to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," to "send information identifying the server selected transmission path for each of the clients to the respective clients," and to "maintain a client link tree having client link entries representing each of the plurality of clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. "[M]aintaining a client link tree having client link entries representing each of the plurality of clients" does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is

The '496 Patent – Claims	Reasons for Patent Ineligibility
	in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic packet radio communication in a networked environment. The claimed networking elements do not provide "significantly more" as *Alice*

The '496 Patent – Claims	Reasons for Patent Ineligibility
modem,	requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said	The "initiates and selects" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur.

The '496 Patent – Claims	Reasons for Patent Ineligibility
server through at least one the remainder of said plurality of clients,	The recitation that the path is "one of a direct link to said server and an indirect link to said server" does not save the claim from abstraction because "one of a direct link to said server and an indirect link to said server" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients,	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

The '496 Patent – Claims	Reasons for Patent Ineligibility
and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	The "server process" clause is abstract. It adds that the server process is configured to "receive information identifying the selected transmission path from each of the plurality of clients," to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," and to "send information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
3. A wireless network system as recited in claim 2, wherein said server process is further configured to:	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim.

The '496 Patent – Claims	Reasons for Patent Ineligibility
compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client

The '496 Patent – Claims	Reasons for Patent Ineligibility
	link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with

The '496 Patent – Claims	Reasons for Patent Ineligibility
	respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
5. The wireless network system of claim 2, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. The claim adds that the "client link entries correspond to the server selected transmission path between the server and the respective client," which does not add "significantly more" to the abstract radio network, particularly due to the vague reference to "correspond." In a network environment, processes that update a network map are common. Thus, the recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Moreover, the "server selected" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, maintaining an

The '496 Patent – Claims	Reasons for Patent Ineligibility
	updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping functions," "clients," and "wireless communication") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients,	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients,	The "server process" clause is abstract. It adds that the server process is configured to "receive information identifying the selected transmission path from each of the plurality of clients," to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," to "update the client link entries to provide the server selected

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the server selected transmission path, and send information identifying the server selected transmission path for each of the clients to the respective clients.	transmission path," and to "send information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept.

The '496 Patent – Claims	Reasons for Patent Ineligibility
comparison meets predetermined conditions.	The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of

The '496 Patent – Claims	Reasons for Patent Ineligibility
	new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. The claim adds that the "client link entries correspond to the server selected transmission path between the server and the respective client.," which does not add "significantly more" to the abstract radio network, particularly due to the vague reference to "correspond." In a network environment, processes that update a network map are common. Thus, the recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Moreover, the "server selected" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, maintaining an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping functions," "clients," and "wireless network communication") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is

The '496 Patent – Claims	Reasons for Patent Ineligibility
	illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	The "server process" clause is abstract. It adds that the server process "receives information identifying the selected transmission path from each of the plurality of clients," "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," and "sends information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim

The '496 Patent – Claims	Reasons for Patent Ineligibility
	charts included in these responses.
maintains a client link tree having client link entries representing each of the plurality of clients.	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping functions," "clients," and "wireless network communication") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process,"

The '496 Patent – Claims	Reasons for Patent Ineligibility
packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.

The '496 Patent – Claims	Reasons for Patent Ineligibility
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further includes maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process:	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	The "server process" clause is abstract. It adds that the server process "receives information identifying the selected transmission path from each of the plurality of clients," "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," "updates the client link entries to provide the server selected transmission path," and "sends information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine,

The '496 Patent – Claims	Reasons for Patent Ineligibility
	and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout

The '496 Patent – Claims	Reasons for Patent Ineligibility
	the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link tree if said client is authentic and is not already in said client link tree.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. The claim adds that the "client link entries correspond to the server selected transmission path between the server and the respective client," which does not add "significantly more" to the abstract radio network, particularly due to the vague reference to "correspond." In a network environment, processes that update a

The '496 Patent – Claims	Reasons for Patent Ineligibility
	network map are common. Thus, the recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Moreover, the "server selected" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, maintaining an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping step," "clients," and "data packet transmission") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
least one of the remainder of said plurality of clients,	The recitation that the path is "one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for	The "server process" clause is abstract. It adds that the server process "receives information identifying the selected transmission path from each of the plurality of clients," "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," and "sends information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
each of the clients to the respective clients; and	environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
maintains a client link tree having client link entries representing each of the plurality of clients.	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
17. A method for providing wireless	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101

The '496 Patent – Claims	Reasons for Patent Ineligibility
network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "housekeeping step," "clients," and "data packet transmission") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected	The "server process" clause is abstract. It adds that the server process "receives information identifying the selected transmission path from each of the plurality of clients," "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," "updates the client link entries to provide the server selected transmission path," and "sends information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language

The '496 Patent – Claims	Reasons for Patent Ineligibility
transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and

The '496 Patent – Claims	Reasons for Patent Ineligibility
determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is

The '496 Patent – Claims	Reasons for Patent Ineligibility
	the abstract idea of radio communications and networking. It is patent ineligible under §101.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. The claim adds that the "client link entries correspond to the server selected transmission path between the server and the respective client," which does not add "significantly more" to the abstract radio network, particularly due to the vague reference to "correspond." In a network environment, processes that update a network map are common. Thus, the recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Moreover, the "server selected" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, maintaining an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
21. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing

The '496 Patent – Claims	Reasons for Patent Ineligibility
implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node" and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any controllers and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	The "initiating" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "a link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because it merely recites that the second nodes have an indirect channel of communication. Further, the "initiation" of an indirect communication path does not add significantly more because it merely encompass typical packet radio communications, and is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node	The "updating" and "modifying" clauses are abstract. It adds a process that "dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized." For example, it is not expressed how the link tree is "updated" or "modified," for

The '496 Patent – Claims	Reasons for Patent Ineligibility
link tree so that the data packet transmission path to the first node is optimized.	example, rendering the language abstract, particularly due to the abstract nature of "optimized." Moreover, in a network environment, processes that "update" and "modify" link trees are common. Thus, the clauses are abstract in general because their characteristics are not described, and are abstract in particular because they are in no way implemented in the claim. The "updating" and "modifying" recitations do not add "significantly more" to the abstract radio network of the claim because they are not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "updating" and "modifying" link trees are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present

The '496 Patent – Claims	Reasons for Patent Ineligibility
comparison meets predetermined conditions.	recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
23. A wireless network system as recited in claim 21, wherein said first node process further comprises: logic determining if one of the plurality of said second nodes is	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining" and "inserting," relating to entries in link tree. These steps are routine database type operations,

The '496 Patent – Claims	Reasons for Patent Ineligibility
authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is

The '496 Patent – Claims	Reasons for Patent Ineligibility
	the abstract idea of radio communications and networking. It is patent ineligible under §101.
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "buffer," and "process") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients, e.g., and any wireless transmissions of any data. They do not recite improvements to node structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this

The '496 Patent – Claims	Reasons for Patent Ineligibility
	case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communications between nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same nodes. The core of what the claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
selecting a link to a first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are

The '496 Patent – Claims	Reasons for Patent Ineligibility
	always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	The clause is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "housekeeping functions," and "wireless radio") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients, e.g., and any wireless transmissions of any data. They do not recite improvements to node structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communications between nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same nodes. The core of what the claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes; dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	The "maintaining," "updating" and "rerouting" clauses are abstract. It adds a process "maintaining a second node link tree having second node link entries representing each of the plurality of second nodes; dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.." For example, it is not expressed how the link tree is "maintained" or "updated" or how data packets are "rerouted," for example, rendering the language abstract. Moreover, in a network environment, processes that "update" and "modify" link trees and that "reroute"data packets are common. Thus, the clauses are abstract in general

The '496 Patent – Claims	Reasons for Patent Ineligibility
	because their characteristics are not described, and are abstract in particular because they are in no way implemented in the claim. The "maintaining," "updating" and "rerouting" clauses do not add "significantly more" to the abstract radio network of the claim because they are not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "maintaining," "updating" and "rerouting" are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims.

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic;	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract.

The '496 Patent – Claims	Reasons for Patent Ineligibility
deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.

The '496 Patent – Claims	Reasons for Patent Ineligibility
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "housekeeping functions," and "wireless radio") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "process" and a generic "wireless radio," but does not specify any structures that improve the process or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any processes and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs

The '496 Patent – Claims	Reasons for Patent Ineligibility
	should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes, dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes,	The "maintaining," "updating" and "rerouting" clauses are abstract. It adds a process "maintaining a second node link tree having second node link entries representing each of the plurality of second nodes, dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes." For example, it is not expressed how the link tree is "maintained" or "updated" or how data packets are "rerouted," for example, rendering the language abstract. Moreover, in a network environment, processes that "update" and "modify" link trees and that "reroute"data packets are common. Thus, the clauses are abstract in general because their characteristics are not described, and are abstract in particular because they are in no way implemented in the claim.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The "maintaining," "updating" and "rerouting" clauses do not add "significantly more" to the abstract radio network of the claim because they are not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "maintaining," "updating" and "rerouting" are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
the second node configured to implement a second node process including: sending and receiving data packet via a second node wireless radio; maintaining a send/receive data buffer in a digital memory; and	This element only recites the most basic, general radio networking structure including generic terms (such as, "node," "wireless radio," and "buffer") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "second nodes." They are said to include a generic "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients and any wireless transmissions of any data. They do not recite improvements to radio communications structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the link is "one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every link must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is

The '496 Patent – Claims	Reasons for Patent Ineligibility
	illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. This element only recites the most basic, general radio networking structure including generic terms (such as, "node," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "second nodes." They are said to include a generic "controller" implementing a "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any processes and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional

The '496 Patent – Claims	Reasons for Patent Ineligibility
	activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	The "initiating" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "a direct link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because it merely recites that the second nodes have an indirect channel of communication. Further, the "initiation" of an indirect communication path does

The '496 Patent – Claims	**Reasons for Patent Ineligibility**
	not add significantly more because it merely encompass typical packet radio communications, and is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
the first node comprising: a first node controller; and a first node radio modem, wherein said first node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting data packets via said first node radio modem; and	This element only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "first node." They are said to include a generic "controller" implementing a "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes and any wireless transmissions of any data. They do not recite improvements to radio communications structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	The "second node link tree" clause is abstract. It adds "maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes," which does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way

The '496 Patent – Claims	Reasons for Patent Ineligibility
	implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claims add manipulations to a link tree, such as "determining" and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act.

The '496 Patent – Claims	Reasons for Patent Ineligibility
comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and	The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim element only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "first node." It is said to include a generic "controller" implementing a "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes and any wireless transmissions of any data. They do not recite improvements to radio communications structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry

The '496 Patent – Claims	Reasons for Patent Ineligibility
	because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	The "second node link tree" clause is abstract. It adds "maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes," which does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said	This element only recites the most basic, general radio networking structure including generic terms (such as, "node," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to

The '496 Patent – Claims	Reasons for Patent Ineligibility
second node radio modem,	the structure of the "second nodes." They are said to include a generic "controller" implementing a "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with any processes and any radios making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	The "initiating" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "a direct link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because it merely recites that the second nodes have an indirect channel of communication. Further, the "initiation" of an indirect communication path does not add significantly more because it merely encompass typical packet radio communications, and is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

The '496 Patent – Claims	Reasons for Patent Ineligibility
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "node" and "R.F. transmission") to communicate. With regard to the steps, there is no improvement identified with respect to the structure of the "nodes." It is said to include a generic "process," but does not specify any steps that improve the node. Instead, the node simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to nodes and is nothing more than abstraction of a generic radio communication in a wireless environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes with processes making any transmissions of any data. They do not recite improvements to wireless communication structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The "selecting" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
	from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	The "second node link tree" clause is abstract. It adds "maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node," which does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. This claim adds comparing a link to an entry in the link tree and updating the tree. Comparing selected entries against existing tables and updating the table based on the comparison is an abstract database concept. The claims are not directed to any specific improvement in the tree or the comparison or updating operations. They simply define the abstract comparison and update

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
when said comparison meets at least one of several predetermined conditions.	generically, particularly with regard to the vague concept of "predetermined conditions." It should be noted that the client link tree was not said to operate in any manner and were not used in any operative way in the base claim. Thus, the present recitation of "comparing" and "updating" has no further significance beyond abstract table operations since the table has no operative effect in either the base claims or this dependent one. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The client link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That they are compared and updated is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions using an updated client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. The claim is patent ineligible under §101.
39. A method as recited in claim 37, wherein said first node process	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim.

The '496 Patent – Claims	Reasons for Patent Ineligibility
further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	This claims add manipulations to a link tree, such as "determining," "deleting," and "inserting," relating to entries in link tree. These steps are routine database type operations, namely verifying table entries, checking for duplicate table entries, and deleting and adding table entries. The claims do not indicate that these operations are novel or unique beyond their abstract data table operations. Comparing authentic entries against existing tables and updating the table based on the authentication is abstract. The claims are not directed to any specific improvement in the tables or the authentication or modification operations. They simply define the abstract use of a data table generically. These claims add no more detail to how the link trees are operational within the whole system. Thus, the present recitations of "authenticating," etc. have no further significance beyond abstract table operations since the tabled have no operative effect in either the base claims or these dependent ones. The tree remains abstract in general because its characteristics are not described, and abstract in particular because it is in no way implemented in the claims. The elements of the dependent claims also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional data table operations. The link tree recitations themselves add nothing more to the abstraction, as described with respect to the base claims. That potential entries are authenticated, added and deleted is no more than the original data tree abstraction. The maintenance of data entries is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The comparison of new links and the updating of a table based thereon are nothing more than the original abstract table maintenance.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic radio communications network using an updated/maintained client link tree. The core of what this claim is doing is the abstract idea of radio communications and networking. It is patent ineligible under §101.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller implementing a server process,	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The claim only recites the most basic, general radio networking structure including generic terms (such as, "server node," "client nodes," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server node" or "client node." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a gateway environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers

The '496 Patent – Claims	Reasons for Patent Ineligibility
	and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server. Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
said server process configured to: receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and	The "server process" clause is abstract. It adds that the server process is configured to "receive information identifying selected transmission paths from each of the plurality of client nodes," "determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes," "send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client

The '496 Patent – Claims	Reasons for Patent Ineligibility
an indirect link to said server node through at least one other client node; determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and maintain a client link tree having client link entries representing each of the plurality of client nodes.	node," and "maintain a client link tree having client link entries representing each of the plurality of client nodes." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. "[M] aintain a client link tree having client link entries representing each of the plurality of client nodes" does not add any meaningful limitation to a tree due to the abstract nature of "entries." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses. The recitation that the path is "one of a direct link to the server node and an indirect link to said server node through at least one other client node" does not save the claim from abstraction because "direct" or "indirect" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of

The '496 Patent – Claims	Reasons for Patent Ineligibility
	abstraction. Further, the presence of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time making it no option at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available then the recitation is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract network may be implemented.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. In addition, performing "gateway functions" does not add "significantly more" to the abstract radio network of the claim. Further, that gateway functions is abstract concept and, at most, are well-understood, routine, and conventional activities, as shown and described throughout the prior art claim charts included in these responses.
42. A server for use in a wireless network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map. The

The '496 Patent – Claims	Reasons for Patent Ineligibility
controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	claim only recites the most basic, general radio networking structure including generic terms (such as, "server," "controller," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a networked environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of client path radio communication to a server. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through clients to a server.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than a generic server and generic clients communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic servers and clients. The core of what the claim is doing is the abstract idea of data networking through clients to a server. The claim is patent ineligible under §101.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	The "initiates and selects" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "one of a direct link to said server and an indirect link to said server" does not save the claim from abstraction because "one of a direct link to said server and an indirect link to said server" are exclusive mutual opposites such that every path must be one or the other. That recitation is the height of abstraction. Further, the "selection" of one of the two exclusive mutual opposites is also nothing more than abstraction because (1) if the claim does not require that both options are always available at any one time from which the "selection" is made then the selection boils down to no option (and hence no selection) at all, which is as abstract as it is illogical, (2) if the claim requires both options are always available at any one time from which the "selection" is made then the selection is nothing more than the abstract idea of sending data directly to a destination or through an intermediary. In the latter case, the claim recites nothing about the improvement, value or parameters by which such abstract selection may be implemented.

The '496 Patent – Claims	Reasons for Patent Ineligibility
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem,	This element only recites the most basic, general radio networking structure including generic terms (such as, "server," "controller," "clients," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "server" or "client." It is said to include a generic "controller" and a generic "radio modem," but does not specify any structures that improve the controller or radio modem. Instead, the controller simply communicates data in a well-known manner. Thus, the claim language is ubiquitous to controllers and radio communications and is nothing more than abstraction of a generic radio communication in a networked environment. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any servers and any clients with any controllers and any radios making any transmissions of any data. They do not recite improvements to server or client structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).
maintaining a client link tree having client link entries representing each of the plurality of clients, and	The "client link tree" clause is abstract. It adds "a client link tree having client link entries," and further recites "representing each of the plurality of clients," which does not add any meaningful limitation to a tree or its entries due to the abstract nature of "representing." Thus, the tree is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The tree recitation does not add "significantly more" to the abstract radio network of

The '496 Patent – Claims	Reasons for Patent Ineligibility
	the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, the maintenance of such a tree is well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
receiving information identifying the selected transmission path from each of the plurality of clients, determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients.	The remainder of the "server process" clause is also abstract. It adds that the server process includes "receiving information identifying the selected transmission path from each of the plurality of clients," "determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients," and "sending information identifying the server selected transmission path for each of the clients to the respective clients." Receiving data is a well-known concept, and does not add "significantly more" to the abstract radio network. With regard to "determining," it is not expressed how the "selected" transmission paths are "determined," for example, rendering the language abstract, particularly due to the abstract nature of "selected." Moreover, in a network environment, processes that update a network map are common, as is the notification to other nodes of an updated map, as called for in the claimed "sending" process. Thus, the "server process" recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Further, the "server process" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, determining, maintaining, and distributing an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.

The '496 Patent – Claims	Reasons for Patent Ineligibility
44. The server of claim 42, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	The asserted dependent patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act for the reasons stated with regard to its base claim. The claim adds that the "client link entries correspond to the server selected transmission path between the server and the respective client," which does not add "significantly more" to the abstract radio network, particularly due to the vague reference to "correspond." In a network environment, processes that update a network map are common. Thus, the recitation is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. Moreover, the "server selected" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, maintaining an updated network map is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
45. A first node for use in wireless network system including a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, receiving and transmitting	The asserted patent claim is patent-ineligible as a matter of law under 35 U.S.C. § 101 of the Patent Act. The claim is not directed to any specific improvement that would advance radio network transmissions but instead articulates only the abstract idea of establishing generic communication between generic components using an optimal map.

The '496 Patent – Claims	Reasons for Patent Ineligibility
data packets via said second node radio modem,	The claim element only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "first node" or "second node." They are said to include a generic "controller" implementing a "process," but does not specify any structures that improve the wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes and any wireless transmissions of any data. They do not recite improvements to radio communications structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses). Step one of the *Mayo* analysis is clearly satisfied as a matter of law. The claims in this case are directed to an ineligible abstract idea that, if allowed, would result in monopolization of the entire field of radio communication with nodes. Plaintiffs should not be allowed to foreclose this broad area with an abstract patent. The elements of the asserted claim also do not pass step two of the *Alice* inquiry because they are all directed to routine, conventional activity for sending radio transmissions through nodes.

The '496 Patent – Claims	Reasons for Patent Ineligibility
	Even in an ordered combination, the claim elements do not pass Section 101 scrutiny because they describe nothing more than generic nodes communicating generic data via generic radio transmissions. Such communications were known in packet radio networks using the same generic nodes. The core of what the claim is doing is the abstract idea of data networking through using nodes. The claim is patent ineligible under §101.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	The "initiating" limitation fails to recite anything more than an abstraction. The claimed selection does not result in communication and, at least under Plaintiffs' implied constructions, are merely a step that must be done for communications to occur. The recitation that the path is "a link to said first node through at least one of the remainder of said plurality of second nodes" does not save the claim from abstraction because it merely recites that the second nodes have an indirect channel of communication. Further, the "initiation" of an indirect communication path does not add significantly more because it merely encompass typical packet radio communications, and is a well-understood, routine, and conventional activity, as shown and described throughout the prior art claim charts included in these responses.
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first	The claim element only recites the most basic, general radio networking structure including generic terms (such as, "nodes," "controller," and "radio modem") to communicate. With regard to the components, there is no improvement identified with respect to the structure of the "first node." It is said to include a generic "controller" implementing a "process," but does not specify any structures that improve the

Exhibit B101 – Invalidity Chart for Brownrigg Family Based on 35 U.S.C. § 101 Patent Eligibility

The '496 Patent – Claims	Reasons for Patent Ineligibility
node radio modem, and	wireless communication. Instead, the processes simply communicate data in a well-known manner. Thus, the claim language is ubiquitous to radio communications and is nothing more than abstraction of a generic radio communication. The claimed networking elements do not provide "significantly more" as *Alice* requires. These elements are merely any nodes and any wireless transmissions of any data. They do not recite improvements to radio communications structures. Further these elements are known in the art, and are admitted prior art and are thus exactly the well-understood, routine, conventional activity described in *Mayo* (as evidenced in the prior art claim charts included in these responses).
dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	The "updating" clause is abstract. It adds a process that "dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized." For example, it is not expressed how the link tree is "updated" or the path "optimized," for example, rendering the language abstract, particularly due to the abstract nature of "optimized." Moreover, in a network environment, processes that "update" link trees are common. Thus, the clause is abstract in general because its characteristics are not described, and is abstract in particular because it is in no way implemented in the claim. The "updating" recitation does not add "significantly more" to the abstract radio network of the claim because it is not otherwise mentioned, used, or implemented in the claim, e.g., in the transmission of data. Further, "updating" link trees is a well-understood, routine, and conventional activity, as shown and described throughout

	the prior art claim charts included in these responses.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

Invalidity Chart for U.S. Patent No. 6,249,516

The '516 Patent – Claims	
1. A server providing a gateway between two networks, where at least one of the two networks is a wireless network, said server comprising: a radio modem capable of communicating with a first network that operates, at least in part, by wireless communication; a network interface capable of communicating with a second network; and a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. Regarding this element, the specification of the '516 patent does not clearly link the claimed functions associated with the "passing" limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform "passing" as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
said digital controller maintaining a map of data packet transmission paths of a plurality of clients of said first network, where a transmission path of a client of said first network to said server can be through one or more of other clients of said first network;	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '516 patent does not clearly link the claimed functions associated with the "maintaining a map of data transmission paths" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a map of data packet transmission paths as claimed.
wherein said digital controller changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose that the server "changes the transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group…". Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the

The '516 Patent – Claims	
	server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be

The '516 Patent – Claims	
	updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
	informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server changes client paths, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path.

The '516 Patent – Claims	
	Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers gateway optimization of paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '516 patent does not clearly link the claimed functions associated with the "changes the transmission paths" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform changes to "the transmission paths" as claimed. The optimization and "most robust" recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as

The '516 Patent – Claims	
	"optimal" or "most robust," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the optimization can involve multiple factors, despite the language "chosen from the group consisting essentially of," the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
2. A server as recited in claim 1, wherein the second network is a TCP/IP protocol network.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.
4. A server as recited in claim 1, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller translates data packets received from the first network and	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Moreover, the specification of the '516 patent does not clearly link the claimed functions associated with the translating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform translation as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
destined for the second network into a format used by the second network.	
5. A server as recited in claim 2: wherein the digital controller receives data packets from the TCP/IP protocol network destined for a client of the first network, adds a header that includes an address of the client of the first network and a data transmission path to the client of the first network, adds a indicator of the type of data associated with the packet, and transmits the packet via the radio modem with the header and the indicator; and wherein the digital controller receives data packets from the first network destined for the TCP/IP protocol network, converts the data packets into TCP/IP format, and sends the TCP/IP format data packet to an IP address on the TCP/IP protocol network.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Moreover, the specification of the '516 patent does not clearly link the claimed functions associated with the translating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform translation as claimed.
10. A method providing a gateway between a wireless network and a	This claim is invalid under 35 U.S.C. § 112.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
second network comprising: receiving a data packet from a client of said wireless network, converting said data packet to a proper format for said second network, and sending said data packet to said second network; and receiving a data packet from said second network, adding a header to said packet including a reverse link and a data packet type if said data packet is destined for a client of said wireless network, said reverse link being one of a direct link to said client and an indirect link to said client through one or more other clients of said network, and transmitting said data packet with said header; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. Regarding this element, the specification of the '516 patent does not clearly link the claimed functions associated with the receiving limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform receiving as claimed. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
changing transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group consisting essentially of the path to the gateway through the least possible number of additional clients, the path to the gateway through the most robust additional	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a gateway that changes "transmission paths of clients to optimize the transmission paths including changing the transmission path from the client to the gateway so that the path to the gateway is chosen from the group …". Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the

The '516 Patent – Claims	
clients, the path to the gateway through the clients with the least amount of traffic, and the path to the gateway through the fastest clients.	clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be

The '516 Patent – Claims	
	appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when

The '516 Patent – Claims	
	clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a gateway performs optimization of paths selected by clients. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o.

The '516 Patent – Claims	
	The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained.

The '516 Patent – Claims	
	Moreover, the specification of the '516 patent does not clearly link the claimed functions associated with the "changing the transmission path" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform "changing the transmission path" as claimed. The optimization and "most robust" recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal" or "most robust," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, despite the language "chosen from the group consisting essentially of," the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
11. A method as recited in claim 10: wherein the second network is a TCP/IP protocol network;	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
wherein the data packet received from a client of a wireless network is converted to a TCP/IP format if it is destined for an IP address on a TCP/IP protocol network, and the TCP/IP format data packet is sent to the IP address on the TCP/IP protocol network; and wherein the data packet received from the second network is received from the TCP/IP protocol network.	Moreover, the specification of the '516 patent does not clearly link the claimed functions associated with the translating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform translation as claimed.
13. A method as recited in claim 10 further comprising maintaining a map of data packet transmission paths of a plurality of clients of the wireless network, where a transmission path of a client of the wireless network to the server can be through one or more other clients of the first network.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Further, the specification of the '516 patent does not clearly link the claimed functions associated with the "maintaining a map of data transmission paths" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a map of data packet transmission paths as claimed.
14. A method as recited in claim 13, further comprising dynamically updating the map of data packet transmission paths to optimize the data packet transmission paths of the	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Further, the claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient

The '516 Patent – Claims	
clients.	written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a gateway that "dynamically update[es] the map of data packet transmission paths to optimize the data packet transmission paths of the clients." Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '516 Patent – Claims	
	data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that

The '516 Patent – Claims	
	server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Invalidity Chart for U.S. Patent No. 8,000,314

The '314 Patent – Claims	
1. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller and a second node radio modem, said second node controller implementing a second node process that includes controlling of said second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	The claim is invalid under 35 U.S.C. § 112.
wherein said second node process of each of said second nodes includes selecting a radio transmission path to said first node that is direct or	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
through at least one of the remainder of said plurality of second nodes; and	The specification of the '314 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained.
wherein said selected path to said first node utilizes the least number of other second nodes, such that said transmission path from each of said second nodes to said first node is optimized and the first node controller implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node, as claimed, that "implements changes to upgrade the selected transmission path in response to a request from at least one of said second nodes." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "upgrade" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client

The '314 Patent – Claims	
	18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16

The '314 Patent – Claims	
	through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7.

The '314 Patent – Claims	
	"In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server upgrades paths selected by clients. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the

The '314 Patent – Claims	
	description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server upgrades of paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the upgrade limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform upgrading as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed upgrading can involve multiple factors, the specification fails to disclose or enable an upgrading algorithm of

The '314 Patent – Claims	
	that employs multiple factors in such a process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-upgrading process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
4. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver configured to receive a data packet from a second node of said wireless network, a first converter configured to convert the data packet to a format used in said second network, and a data packet sender configured to send the data packet to a proper location on said second network; and a second data packet receiver configured to receive the data packet from said second network, a second converter configured to convert the data packet to a format used in said	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. Regarding this element, the specification of the '314 patent does not clearly link the claimed functions associated with the converting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform converting as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
wireless network, and a data packet sender configured to send said data packet with a header to a second node of said wireless network; and	
a controller configured to implement changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group consisting essentially of the path to first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a gateway that implements "changes to a transmission path from the second node to the first node based upon viable network paths observed by the second node so that the path to the first node is chosen from the group…". Instead, the specification discloses that the client selects paths to the server and the client changes those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client

The '314 Patent – Claims	
	18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
	through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7.

The '314 Patent – Claims	
	"In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server changes paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the

The '314 Patent – Claims	
	description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server changing paths for optimization, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the "changing the transmission paths" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform "changing the transmission paths" as claimed. The "most robust" recitation also renders the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "most robust," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed changing can involve multiple factors, despite the language "chosen from the group consisting essentially

The '314 Patent – Claims	
	of," the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
10. A client node in a network including a server node having a server radio modem and a server controller which implements a server process that includes controlling the server node to receive and transmit data packets via said server node to other nodes in the network, the client node comprising: a client node radio modem; and a client node controller; said client node controller implementing a process including receiving and transmitting data packets via said client modem;	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the server found in the preamble, as the body of the claim does not make clear which features of the server are related to the features recited in the body of the claim. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the server found in the preamble, as the body of the claim does not make clear which features of the server are related to the features recited in the body of the claim.
selecting a radio transmission path to said server node that is one of a direct	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written

The '314 Patent – Claims	
link to said server node and an indirect link to said server node through at least one other client node;	description to enable the full scope of the claimed invention. The specification of the '314 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the client node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
implementing a process requesting updated radio transmission path data from said server node, and in response thereto, implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose "implementing by the server node changes to upgrade the selected transmission path to an optimized transmission path." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "upgrade" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to

The '314 Patent – Claims	
	control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
	path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7

The '314 Patent – Claims	
	currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server upgrades paths selected by clients. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the

The '314 Patent – Claims	
	digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server upgrades of paths of the clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the changes to upgrade limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform changes to upgrade as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
	The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
12. A first node providing a gateway between two networks, where at least one of the two networks is a wireless network, said first node comprising: a radio modem capable of communicating with a first network that operates in part, by wireless communication; a network interface to communicating with a second network;	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. Regarding this element, the specification of the '314 patent does not clearly link the claimed functions associated with the "passing" limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform "passing" as claimed.

The '314 Patent – Claims	
a digital controller coupled to said radio modem and to said network interface, said digital controller communicating with said first network via said radio modem and communicating with said second network via said network interface, said digital controller passing data packets received from said first network that are destined for said second network to said second network, and passing data packets received from said second network that are destined for said first network to said first network,	
said digital controller maintaining a map of data packet transmission paths to a plurality of second nodes of said first network, where a transmission path of a second node of said first network to said first node can be through one or more of other second node of said first network;	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '314 patent does not clearly link the claimed functions associated with the "maintaining a map of data packet transmission paths" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a map of data packet transmission paths as claimed.
wherein said digital controller changes the transmission paths of each of the second nodes to optimize the transmission paths including	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	The limitation "from on of the plurality" is indefinite. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose "chang[ing] the transmission paths of each of the second nodes to optimize the transmission paths including changing each transmission path from on of the plurality of said second nodes to the first node so that the path to the first node is chosen from the group….," to the extent "from on of the plurality" has any meaning. Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
	hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67.

The '314 Patent – Claims	
	"As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21.

The '314 Patent – Claims	
	In contrast, nothing in the Brownrigg patents discloses that a gateway optimizes paths selected by clients. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from

The '314 Patent – Claims	
	the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers gateway optimization of paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the gateway's actions cannot be reasonably ascertained. Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the changes to optimize limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform changes to optimize as claimed. The optimization and "most robust" recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal" or "most robust," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, despite the language "chosen from the group consisting essentially of," the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a gateway. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
	preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
13. A first node as recited in claim 12, wherein the digital controller translates data packets received from the second network and destined for the first network into a format used by the first network, and the digital controller converts data packets received from the first network and destined for the second network into a format used by the second network.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the translating and converting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform translation and converting as claimed.
14. A first node providing a gateway between a wireless network and a second network, the first node comprising: a first data packet receiver implementing a process to receive a data packet from a second node of said wireless network, a first converter implementing a process to convert said data packet to a format	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '314 patent does not clearly link the claimed functions associated with the converting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform converting as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '314 Patent – Claims	
used in said second network, and a first transmitter implementing a process to transmit said data packet to a proper location on said second network; and a second data packet receiver implementing a process to receive a data packet from said second network, a second converter implementing a process to convert said data packet to a format used in said wireless network, and a second transmitter implementing a process to transmit said data packet with a header to a second node of said wireless network; and	
a controller implementing a process to change a transmission path to optimize a transmission path includes changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group consisting essentially of the path to the first node through the least possible number of additional second nodes, the path to the first node through the most robust additional second nodes, the path to	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node, as claimed, that "implement[s]a process to change a transmission path to optimize a transmission path includ[ing] changing the transmission path from the second node to the first node so that the path to the first node is chosen from the group…" Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other

The '314 Patent – Claims	
the first node through the second nodes with the least amount of traffic, and the path to the first node through the fastest second nodes.	Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or

The '314 Patent – Claims	
	optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a

The '314 Patent – Claims	
	server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server optimizes paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o.

The '314 Patent – Claims	
	The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a gateway that optimizes paths of second nodes, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the gateway's actions cannot be reasonably ascertained.

The '314 Patent – Claims	
	Moreover, the specification of the '314 patent does not clearly link the claimed functions associated with the optimizing limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimizing as claimed. The optimization and "most robust" recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal" or "most robust," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, despite the language "chosen from the group consisting essentially of," the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a gateway. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-upgrading process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.

Invalidity Chart for U.S. Patent No. 8,233,471

The '471 Patent – Claims	
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	This claim is invalid under 35 U.S.C. § 112.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the initiating and selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	perform initiating and selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in initiating and selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further includes logic that maintains a client link tree having client link entries corresponding to an optimized transmission path for each of the plurality of clients, and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries corresponding to" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed correspondence.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to

The '471 Patent – Claims	
path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	sufficiently disclose a server process, as claimed, configured to "determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of

The '471 Patent – Claims	
	data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that

The '471 Patent – Claims	
	server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server optimizes paths

The '471 Patent – Claims	
	selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification.

The '471 Patent – Claims	
	As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a server that optimizes paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the optimization limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimization as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	patent at 9:11-16. Moreover, the limitation "send the optimized transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "optimized transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send the optimized transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "the optimized transmission path" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
3. A wireless network system as recited in claim 2, wherein said server process further comprises: logic that compares a selected link from said client to said server to a current client link entry in said client link tree; and logic that updates said client link tree when said comparison meets	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
predetermined conditions.	be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
4. A wireless network system as recited in claim 3, wherein said server process further comprises: logic that determines if said client is authentic; logic that determines if said client is already in said client link tree if client is determined to be authentic; logic that deletes said client from said client link tree if said client is already in said client link tree; and logic that inserts said client in said client link tree if said client is authentic.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
6. A wireless network system comprising: a server providing a server process including: receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping function, and the specification fails to adequately disclose the scope of such functions.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further comprises maintaining a client link tree having client link entries corresponding to an optimized transmission path for each of the	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the "maintaining a client link tree having client link entries" limitation to a disclosed

The '471 Patent – Claims	
plurality of clients, and	algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries corresponding to" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed correspondence.
wherein the server process is configured to: receive the selected transmission path from each of the plurality of clients, determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, configured to "determine the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the optimized transmission path, and send the optimized transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the

The '471 Patent – Claims	
	server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be

The '471 Patent – Claims	
	updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7

The '471 Patent – Claims	
	informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server optimizes paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path.

The '471 Patent – Claims	
	Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a server that optimizes paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the optimization limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimization as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a

The '471 Patent – Claims	
	subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send the optimized transmission path for each of the clients to the respective clients" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send the optimized transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "the optimized transmission path" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.

The '471 Patent – Claims	
7. A wireless network system as recited in claim 6, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is already in said client link tree; and insert said client in said client link tree if said client is authentic.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.

The '471 Patent – Claims	
10. A method for providing wireless network communication comprising: providing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and providing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping function, and the specification fails to adequately disclose the scope of such functions.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is

The '471 Patent – Claims	
	not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein the server process: receives the selected transmission path from each of the plurality of clients determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client

The '471 Patent – Claims	
	18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16

The '471 Patent – Claims	
	through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7.

The '471 Patent – Claims	
	"In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server optimizes paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the

The '471 Patent – Claims	
	description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a method of server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the optimization limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimization as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sends the optimized transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "optimized transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends the optimized transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "the optimized transmission path" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
11. A method as recited in claim 10,	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. §

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
12. A method as recited in claim 11, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and inserting said client in said client link tree if said client is authentic.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
14. A method for providing wireless network communication comprising the steps of:	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	limitation "housekeeping step" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping step, and the specification fails to adequately disclose the scope of such functions.
a link selection step that is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the link selection limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform link selection as claimed. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further comprises the step of maintaining a client link tree having client link entries corresponding to an optimized	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
transmission path for each of the plurality of clients, and	maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries corresponding to" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed correspondence.
wherein the server process: receives the selected transmission path from each of the plurality of clients, determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines the optimized transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the optimized transmission path, and sends the optimized transmission path for each of the clients to the respective client." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network.

The '471 Patent – Claims	
	The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client

The '471 Patent – Claims	
	7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a method of server optimization of paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an

The '471 Patent – Claims	
	optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a method of server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the optimization limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimization as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the

The '471 Patent – Claims	
	invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sends the optimized transmission path for each of the clients to the respective client" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "optimized transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends the optimized transmission path for each of the clients to the respective client" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "the optimized transmission path" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm

The '471 Patent – Claims	
	that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
15. A method as recited in claim 14, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
16. A method as recited in claim 15, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is already in said client link tree; and	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
inserting said client into said client link tree if said client is authentic.	
17. A wireless network system comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	This claim is invalid under 35 U.S.C. § 112.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the initiating limitations to a disclosed algorithm that performs each

The '471 Patent – Claims	
nodes; and	of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained.
wherein said first node process dynamically updates a second node link tree comprising second node link entries and dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process "dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized." Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64.

The '471 Patent – Claims	
	"It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a first node process, as claimed, that dynamically modifies the second node link tree so that the data packet transmission from the first node is optimized. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8)

The '471 Patent – Claims	
	where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a first node that optimizes paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the first node's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the dynamically modifying limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically modifying as claimed. The optimization recitation also renders the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
	a first node as claimed. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
18. A wireless network system as recited in claim 17, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
19. A wireless network system as recited in claim 18 wherein said first	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.

The '471 Patent – Claims	
node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
20. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, and performing node link tree housekeeping functions; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a node link tree housekeeping function, and the specification fails to adequately disclose the scope of such functions.

The '471 Patent – Claims	
node wireless radio, maintaining a send/receive data buffer in a digital memory, and	
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
the first node process further comprises maintaining a second node link tree having second node link entries,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the "maintaining a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries.

The '471 Patent – Claims	
	Also, the term "second node link entries" is indefinite because it is unclear what represents an entry.
dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process "dynamically updating the tree to reflect the current operational status of the nodes, and rerouting data packets around inactive or malfunctioning nodes." Instead, the specification discloses that the client selects paths to the server and the clients optimize those paths by rerouting around inactive or malfunctioning nodes. The following portions of the specification support that the clients reroute data packets (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64.

The '471 Patent – Claims	
	"It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and

The '471 Patent – Claims	
	18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a

The '471 Patent – Claims	
	server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server performs rerouting of data packets in the manner claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct

The '471 Patent – Claims	
	path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a server that reroutes data packets, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the dynamically updating and rerouting limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically updating and rerouting as claimed. Moreover, to the extent that SIPCO contends that the claimed rerouting can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a first node as claimed. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to

The '471 Patent – Claims	
	stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
21. A wireless system as recited in claim 20, wherein the first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
22. A wireless system as recited in claim 21, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic.	
31. A wireless system comprising: a first node implementing a first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, and communicating with a network; a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	This claim is invalid under 35 U.S.C. § 112.
selecting a link to said first node that is one of a direct link to said first node and an indirect link to said first node	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
through at least one of the remainder of said plurality of second nodes; and	The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
the first node process further comprises maintaining a second node link tree having second node link entries.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the "maintaining a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries" is indefinite because it is unclear what represents an entry.
32. A wireless system as recited in claim 31, wherein the first node process further comprises:	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.

The '471 Patent – Claims	
logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic updating said second node link tree when said comparison meets predetermined conditions.	The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
33. A wireless system as recited in claim 32, wherein the first node process further includes: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; logic deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and logic inserting one of the plurality of said second nodes in said second node	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
link tree if said second node is authentic.	
34. A method for providing wireless network communication comprising: providing a first node implementing a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; providing a plurality of second nodes, each second node providing a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	This claim is invalid under 35 U.S.C. § 112.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second nodes's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite.

The '471 Patent – Claims	
	Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
maintaining a second node link tree having second node link entries at the first node.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the "maintaining a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries" is indefinite because it is unclear what represents an entry.
35. A method as recited in claim 34, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets at least one of several predetermined conditions meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition, how it is predetermined, what the "several" conditions

The '471 Patent – Claims	
conditions.	are, and whether they need to be simultaneously met, and the specification fails to adequately disclose how such function is performed.
36. A method as recited in claim 34, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '471 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising: a server node radio modem; and a server node controller	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the client found in the preamble, as the body of the claim does not make clear which features of the client are related to the features recited in the body of the claim.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '471 Patent – Claims	
implementing a server process, said server process configured to:	
receive selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node;	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '471 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the client node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; and send the optimized transmission path for each of the plurality of client nodes to the respective client node.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, configured to "determine an optimized transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes, and send the optimized transmission path for each of the plurality of client nodes to the respective client node." Instead, the specification discloses that the clients select paths to the

The '471 Patent – Claims	
	server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the

The '471 Patent – Claims	
	number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17.

The '471 Patent – Claims	
	"As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses server optimization of paths selected by clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server

The '471 Patent – Claims	
	process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention.

The '471 Patent – Claims	
	Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the optimization limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform optimization as claimed. The optimization recitations also render the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send the optimized transmission path for each of the plurality of client nodes to the respective client node" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "optimized transmission path"

The '471 Patent – Claims	
	is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send the optimized transmission path for each of the plurality of client nodes to the respective client node" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "the optimized transmission path" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Moreover, the specification of the '471 patent does not clearly link the claimed functions associated with the gateway functions limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform gateway functions as claimed. Moreover, the limitation "perform gateway functions" is indefinite as it cannot be reasonably ascertained what constitutes a gateway function, and the specification fails to adequately disclose how such function is performed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

Invalidity Chart for U.S. Patent No. 8,625,496

The '496 Patent – Claims	
1. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	This claim is invalid under 35 U.S.C. § 112.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating and selecting limitations to a disclosed algorithm that

The '496 Patent – Claims	
remainder of said plurality of clients; and	performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating and selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in initiating and selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients; determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients; send information identifying the server selected transmission path for each of the clients to the respective clients; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, configured to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, [and] send information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to

The '496 Patent – Claims	
	control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication

The '496 Patent – Claims	
	path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7

The '496 Patent – Claims	
	currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example

The '496 Patent – Claims	
	refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed.

The '496 Patent – Claims	
	Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not

The '496 Patent – Claims	
	clearly perform sending as claimed.
maintain a client link tree having client link entries representing each of the plurality of clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
2. A wireless network system comprising: a server including a server controller and a server radio modem, said server controller implementing a server process that includes the control of said server radio modem, said server process including the receipt and transmission of data packets via said server radio modem; and a plurality of clients each including a client controller and a client radio modem, said client controller	This claim is invalid under 35 U.S.C. § 112.

The '496 Patent – Claims	
implementing a client process that includes the control of said client radio modem, said client process including the receipt and transmission of data packets via said client radio modem,	
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating and selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating and selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in initiating and selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further includes logic that maintains a client link tree having client link entries representing each of the plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms

The '496 Patent – Claims	
	do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
and wherein the server process is configured to: receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, configured to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and send information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6.

The '496 Patent – Claims	
	"If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at

The '496 Patent – Claims	
	9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream'

The '496 Patent – Claims	
	from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected path based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path.

The '496 Patent – Claims	
	Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server.

The '496 Patent – Claims	
	In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
3. A wireless network system as	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. §

The '496 Patent – Claims	
recited in claim 2, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
4. A wireless network system as recited in claim 2, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if said client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
5. The wireless network system of claim 2, wherein the client link entries	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.

The '496 Patent – Claims	
correspond to the server selected transmission path between the server and the respective client.	Also, the term "client link entries correspond to" is indefinite because it is unclear what represents an entry and the scope of the claimed correspondence.
7. A wireless network system comprising: a server providing a server process including receiving data packets via a server wireless communication, sending data packets via said wireless communication, communicating with a network, and performing housekeeping functions; and a plurality of clients, each client providing a client process including sending and receiving data packet via a client wireless communication, maintaining a send/receive data buffer in digital memory, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping function, and the specification fails to adequately disclose the scope of such functions.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
remainder of said plurality of clients,	The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further comprises maintaining a client link tree having client link entries representing each of the plurality of clients, and wherein the server process is configured to:	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
receive information identifying the selected transmission path from each of the plurality of clients, determine a server selected transmission path for each of the	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to

The '496 Patent – Claims	
plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the server selected transmission path, and send information identifying the server selected transmission path for each of the clients to the respective clients.	sufficiently disclose a server process, as claimed, configured to "determine a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, update the client link entries to provide the server selected transmission path, and send information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of

The '496 Patent – Claims	
	data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that

The '496 Patent – Claims	
	server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a

The '496 Patent – Claims	
	server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the

The '496 Patent – Claims	
	clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information

The '496 Patent – Claims	
	identifying the server selected transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "send information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
8. A wireless network system as recited in claim 7, wherein said server process is further configured to: compare a selected link from said client to said server to a current client link entry in said client link tree; and update said client link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
9. A wireless network system as recited in claim 7, wherein said server process is further configured to: determine if said client is authentic; determine if said client is already in said client link tree if client is determined to be authentic; delete said client from said client link tree if said client is authentic and is already in said client link tree; and insert said client in said client link tree if said client is authentic and is not already in said client link tree.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
10. The wireless network system of claim 7, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Also, the terms "client link entries correspond to" is indefinite because it is unclear what represents an entry and the scope of the claimed correspondence.
11. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving data packets via RF transmission, sending data packets via RF	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping function, and the specification fails to adequately disclose the scope of such functions.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in selecting cannot be reasonably ascertained.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, [and] sends information identifying the server selected transmission path for each of the clients to the

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
sends information identifying the server selected transmission path for each of the clients to the respective clients; and	respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a

The '496 Patent – Claims	
	routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these

The '496 Patent – Claims	
	concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server

The '496 Patent – Claims	
	optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues."

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path' is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends information identifying the server selected

The '496 Patent – Claims	
	transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
maintains a client link tree having client link entries representing each of the plurality of clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
12. A method for providing wireless network communication comprising: utilizing a server implementing a server process including receiving	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
data packets via RF transmission, sending data packets via RF transmission, communicating with a network, and performing housekeeping functions; and utilizing a plurality of clients, each client providing a client process including sending and receiving data packet via RF transmission, maintaining a send/receive data buffer in digital memory, and	ascertained what constitutes a housekeeping function, and the specification fails to adequately disclose the scope of such functions.
selecting a transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further includes maintaining a client link tree	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written

The '496 Patent – Claims	
having client link entries representing each of the plurality of clients, and wherein the server process:	description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at

The '496 Patent – Claims	
	least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the

The '496 Patent – Claims	
	wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this

The '496 Patent – Claims	
	path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then

The '496 Patent – Claims	
	sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not

The '496 Patent – Claims	
	clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path' is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "sends information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm

The '496 Patent – Claims	
	that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
13. A method as recited in claim 12, wherein said server process further includes: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
14. A method as recited m claim 12, wherein said server process further includes: determining is said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client in said client link	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
tree if said client is authentic and is not already in said client link tree.	
15. The method of claim 12, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Also, the term "client link entries correspond to" is indefinite because it is unclear what represents an entry and the scope of the claimed correspondence.
16. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping step" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping step, and the specification fails to adequately disclose the scope of such functions.
a transmission path selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention.

The '496 Patent – Claims	
least one of the remainder of said plurality of clients,	The specification of the '496 patent does not clearly link the claimed functions associated with the path selection limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform path selection as claimed. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein the server process: receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, sends information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to

The '496 Patent – Claims	
	control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication

The '496 Patent – Claims	
	path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7

The '496 Patent – Claims	
	currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example

The '496 Patent – Claims	
	refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed.

The '496 Patent – Claims	
	Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path' is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "sends information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not

The '496 Patent – Claims	
	clearly perform sending as claimed.
maintains a client link tree having client link entries representing each of the plurality of clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
17. A method for providing wireless network communication comprising the steps of: a server process including a data packet reception step, a data packet transmission step, a network communication step, and a housekeeping step; and a plurality of clients each providing a client process including a data sending and receiving step, a send and receive data buffer maintenance step, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping step" is indefinite as it cannot be reasonably ascertained what constitutes a housekeeping step, and the specification fails to adequately disclose the scope of such functions.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
a link selection step wherein the transmission path is one of a direct link to a server and an indirect link to said server through at least one of the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the link selection limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform link selection as claimed. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
wherein said server process further comprises the step of maintaining a client link tree having client link entries representing each of the plurality of clients, and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
wherein the server process:	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the

The '496 Patent – Claims	
receives information identifying the selected transmission path from each of the plurality of clients, determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients.	claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, that "determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, updates the client link entries to provide the server selected transmission path, and sends information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64.

The '496 Patent – Claims	
	"It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is

The '496 Patent – Claims	
	upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through

The '496 Patent – Claims	
	server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct

The '496 Patent – Claims	
	path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062

The '496 Patent – Claims	
	patent at 9:11-16. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path' is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "sends information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.
18. A method as recited m claim 17, wherein said server process further comprises the steps of: comparing a selected link from said client to said server to a current client link entry in said client link tree; and updating said client link tree when	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
said comparison meets predetermined conditions.	Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
19. A method as recited in claim 17, wherein said server process further comprises steps of: determining if said client is authentic; determining if said client is already in said client link tree if client is determined to be authentic; deleting said client from said client link tree if said client is authentic and is already in said client link tree; and inserting said client into said client link tree if said client is authentic and is not already in said client link tree.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
20. The method of claim 17, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Also, the term "client link entries correspond to" is indefinite because it is unclear what represents an entry and the scope of the claimed correspondence.
21. A wireless network system	This claim is invalid under 35 U.S.C. § 112.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
comprising: a first node including a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling of said first node radio modem, said first node process including receiving and transmitting data packets via said first node radio modem; a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, said second node process including receiving and transmitting data packets via said second node radio modem,	
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in initiating cannot be reasonably ascertained.

The '496 Patent – Claims	
wherein said first node process dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes and dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process, as claimed, that "dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized." Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission.

The '496 Patent – Claims	
	In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67.

The '496 Patent – Claims	
	"As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without

The '496 Patent – Claims	
	the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a first node process, as claimed, dynamically modifies the second node link tree so that the data packet transmission path to the first node is optimized. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server

The '496 Patent – Claims	
	are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a first node that optimizes paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the first node's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the dynamically modifying limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically modifying as claimed. The optimization recitation also renders the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a first node as claimed. In fact, the specification effectively admits that a multi-factor algorithm is not

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
22. A wireless network system as recited in claim 21, wherein at least one of the second nodes is a mobile device and said first node process further comprises: logic comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and logic dynamically updating said second node link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
23. A wireless network system as recited in claim 21, wherein said first	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim.

The '496 Patent – Claims	
node process further comprises: logic determining if one of the plurality of said second nodes is authentic; logic determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and logic inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said second node link tree.	The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
24. In a wireless system comprising a plurality of second nodes, each second node implementing a second node process including sending and receiving data packet via a second node wireless radio, maintaining a send/receive data buffer in a digital memory, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. The transition of the claim is unclear, and it is not ascertainable what category of statutory subject matter that the claim is directed to (e.g., a method or apparatus). Moreover, it is unclear whether an accused infringer or prior art reference needs to include the recited features of the system found in the preamble, as the body of the claim does not make clear which features of the system are related to the features recited in the body of the claim.
selecting a link to a first node that is one of a direct link to said first node	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written

The '496 Patent – Claims	
and an indirect link to said first node through at least one of the remainder of said plurality of second nodes,	description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
a first node configured to implement a first node process, the first node process including: receiving data packets via a first node wireless radio; sending data packets via said wireless radio; communicating with a network; performing node link tree housekeeping functions;	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably ascertained what constitutes a node link tree housekeeping function, and the specification fails to adequately disclose the scope of such functions.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes;	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a second node link tree having second node link entries" limitation to a

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process "dynamically updating the tree to reflect the current operational status of the second nodes; and rerouting data packets around inactive or malfunctioning second nodes." Instead, the specification discloses that the client selects paths to the server and the clients optimize those paths by rerouting around inactive or malfunctioning nodes. The following portions of the specification support that the clients reroute data packets (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6.

The '496 Patent – Claims	
	"If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at

The '496 Patent – Claims	
	9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream'

The '496 Patent – Claims	
	from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server performs rerouting of data packets in the manner claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path.

The '496 Patent – Claims	
	Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a server that reroutes data packets, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the dynamically updating and rerouting limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically updating and rerouting as claimed. Moreover, to the extent that SIPCO contends that the claimed rerouting can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
25. The first node of claim 24, wherein the first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and dynamically updating said second node link tree when said comparison meets predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.
26. The first node of claim 24, wherein the first node process further includes: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
second node link tree if one of the plurality of said second nodes is determined to be authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node link tree if said second node is authentic and is not already in said client link tree.	with authentication as claimed.
27. In a wireless system comprising a plurality of second nodes and a first node configured to implement a first node process, the first node process including receiving data packets via a first node wireless radio, sending data packets via said wireless radio, communicating with a network, performing node link tree housekeeping functions,	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. The transition of the claim is unclear, and it is not ascertainable what category of statutory subject matter that the claim is directed to (e.g., a method or apparatus). Moreover, it is unclear whether an accused infringer or prior art reference needs to include the recited features of the system found in the preamble, as the body of the claim does not make clear which features of the system are related to the features recited in the body of the claim. The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite. The limitation "housekeeping functions" is indefinite as it cannot be reasonably

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	ascertained what constitutes a node link tree housekeeping function, and the specification fails to adequately disclose the scope of such functions.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process "dynamically updating the tree to reflect the current operational status of the second nodes, and rerouting data packets around inactive or malfunctioning second nodes, a second node in the plurality of second nodes." Instead, the specification discloses that the client selects paths to the server and the clients optimize those paths by rerouting around inactive or malfunctioning nodes. The following portions of the specification support that the clients reroute data packets (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents):

The '496 Patent – Claims	
	"A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at

The '496 Patent – Claims	
	8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28

The '496 Patent – Claims	
	"In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses that a server performs rerouting of data packets in the manner claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a server that reroutes data packets, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	functions associated with the dynamically updating and rerouting limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically updating and rerouting as claimed. Moreover, to the extent that SIPCO contends that the claimed rerouting can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at the server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.
the second node configured to implement a second node process including: sending and receiving data packet via a second node wireless radio; maintaining a send/receive data buffer in a digital memory; and selecting a link to the first node that is one of a direct link to the first node and an indirect link to the first node through at least one of the remainder of the plurality of second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this

The '496 Patent – Claims	
	limitation fails to provide a meaningful limitation to the claimed network.
33. In a wireless network system comprising a plurality of second nodes each including a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, and	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the system and second node found in the preamble, as the body of the claim does not make clear which features of the system and second node are related to the features recited in the body of the claim.
initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The claim is indefinite because a path "through at least one of the remainder of said plurality of second nodes" would be understood by a person of ordinary skill in the art to be an indirect path, and a "direct" link would be understood as passing "through" another peer node. Yet, the claim recites that the "direct" link is "through at least one of the remainder of said plurality of second nodes." That the claim confuses understood meanings of "direct" and "indirect" renders the claim indefinite.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
the first node comprising: a first node controller; and a first node radio modem, wherein said first node controller is configured to implement a first node process comprising: controlling said first node radio modem; receiving and transmitting data packets via said first node radio modem; and maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
34. A wireless network system as recited in claim 33, wherein said first node process further comprises: comparing a selected link from one of the plurality of said second nodes to said first node to a current second node link entry in said second node link tree; and updating said second node link tree when said comparison meet predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meet predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition and how it is predetermined, and the specification fails to adequately disclose how such function is performed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
35. A wireless network system as recited in claim 33, wherein said first node process further comprises: determining if one of the plurality of said second nodes is authentic; determining if one of the plurality of said second nodes is already in said second node link tree if one of the plurality of said second nodes is determined to be authentic; and inserting one of the plurality of said second nodes in said second node link tree if one of the plurality of said second nodes is authentic and is not already in said client link tree.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
36. In a wireless network system comprising a plurality of second nodes and a first node, the first node comprising a first node controller and a first node radio modem, wherein said first node controller is configured to implement a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the system and first node found in the preamble, as the body of the claim does not make clear which features of the system and first node are related to the features recited in the body of the claim.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
node radio modem, and	
maintaining a second node link tree comprising second node link entries representing each of the plurality of second nodes, at least one second node in the plurality of second nodes comprising:	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
a second node controller configured to implement a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem, initiating a radio transmission path to a first node that is a direct link to said first node through at least one of the remainder of said plurality of second nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The claim is indefinite because a path "through at least one of the remainder of said plurality of second nodes" would be understood by a person of ordinary skill in the art to be an indirect path, and a "direct" link would be understood as passing "through" another peer node. Yet, the claim recites that the "direct" link is "through at least one of the remainder of said plurality of second nodes." That the claim confuses

The '496 Patent – Claims	
	understood meanings of "direct" and "indirect" renders the claim indefinite.
37. A method for providing wireless network communication comprising: implementing in a first node a first node process including receiving data packets via R.F. transmission and sending data packets via R.F. transmission; implementing in each of a plurality of second nodes a second node process including sending and receiving data packet via R.F. transmission, maintaining a send/receive data buffer in digital memory, and	This claim is invalid under 35 U.S.C. § 112.
selecting a transmission path to said first node that is one of a direct link to said first node and an indirect link to said first node through at least one of the remainder of said plurality of second nodes; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform selecting as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is

The '496 Patent – Claims	
	not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
maintaining a second node link tree having second node link entries representing each of the plurality of second nodes at the first node.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a second node link tree having second node link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a second node link tree having second node link entries. Also, the term "second node link entries representing" is indefinite because it is unclear what represents an entry and the scope of the claimed representativeness.
38. A method as recited in claim 37, wherein said first node process further includes: comparing a selected link from one of the plurality of said second nodes to said first node to a second node link entry in said second node link tree; and updating said second node link tree when said comparison meets at least one of several predetermined conditions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the comparing and updating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform comparing and updating as claimed. Moreover, the limitation "meets at least one of several predetermined conditions meets predetermined conditions" is indefinite as it cannot be reasonably ascertained what constitutes a condition, how it is predetermined, what the "several" conditions are, and whether they need to be simultaneously met, and the specification fails to

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	adequately disclose how such function is performed.
39. A method as recited in claim 37, wherein said first node process further includes: determining if one of the plurality of said second nodes is authentic; deleting one of the plurality of said second nodes from said second node link tree if one of the plurality of said second nodes is authentic and is already in said second node link tree; and inserting one of the plurality of said second nodes in said second node tree if said second node is authentic and is not already in said client link tree.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. The specification of the '496 patent does not clearly link the claimed functions associated with the authentication (i.e., determining, deleting, inserting) limitations to a disclosed algorithm that performs each of the claimed functions in the manner claimed, and the disclosed algorithms do not clearly perform the functions associated with authentication as claimed.
40. In a network including a plurality of client nodes having a client radio modem and a client controller which implements a client process including receiving and transmitting data packets via said client node to other nodes in the network, a server node comprising:	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the clients found in the preamble, as the body of the claim does not make clear which features of the client are related to the features recited in the body of the claim.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
a server node radio modem; and a server node controller implementing a server process, said server process configured to:	
receive information identifying selected transmission paths from each of the plurality of client nodes, wherein said transmission path is one of a direct link to the server node and an indirect link to said server node through at least one other client node; determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node; and	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server process, as claimed, configured to "determine a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes; [and] send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has

The '496 Patent – Claims	
	less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35.

The '496 Patent – Claims	
	"In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7.

The '496 Patent – Claims	
	"In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server that determines a server selected transmission path for each of the plurality of client nodes based on the selected transmission paths received from the plurality of client nodes, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only

The '496 Patent – Claims	
	that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed. Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not

The '496 Patent – Claims	
	disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "send information identifying the server selected transmission path for each of the plurality of client nodes to the respective client node" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sends information identifying the server selected transmission path for each of the clients to the respective clients" renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "send information identifying the server selected transmission path for each of the plurality of client nodes" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
maintain a client link tree having client link entries representing each of the plurality of client nodes.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
41. The server node of claim 40, wherein the server process is further configured to perform gateway functions.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the gateway functions limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform gateway functions as claimed. Moreover, the limitation "perform gateway functions" is indefinite as it cannot be reasonably ascertained what constitutes a gateway function, and the specification fails to adequately disclose how such function is performed.
42. A server for use in a wireless	This claim is invalid under 35 U.S.C. § 112.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
network system including a plurality of clients each including a client controller and a client radio modem, said client controller implementing a client process that includes controlling said client radio modem, receiving and transmitting data packets via said client radio modem,	The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the system and clients found in the preamble, as the body of the claim does not make clear which features of the system and clients are related to the features recited in the body of the claim.
wherein said client process of each of said clients initiates and selects a radio transmission path to said server that is one of a direct link to said server and an indirect link to said server through at least one the remainder of said plurality of clients,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating and selecting limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating and selecting as claimed. Additionally, this element is indefinite, as the scope of the clients's actions in initiating and selecting cannot be reasonably ascertained. The limitation "one of a direct link … and an indirect link" renders the claim indefinite. Specifically, requiring that the route either to be a "direct link" or an "indirect link" is not in any way limiting. For a "link" to exist, it must be either direct or not. Thus, this limitation fails to provide a meaningful limitation to the claimed network.
said server comprising: a server controller and a server radio modem, said server controller implementing a server process that	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the

The '496 Patent – Claims	
includes the controlling of said server radio modem, receiving and transmitting of data packets via said server radio modem, maintaining a client link tree having client link entries representing each of the plurality of clients, and	maintaining "a client link tree having client link entries" limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly "maintain" a client link tree having client link entries. Also, the terms "client link tree" and "client link entries representing" are indefinite because it is unclear what represents a tree, an entry, and the scope of the claimed representativeness.
receiving information identifying the selected transmission path from each of the plurality of clients, determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a server controller, as claimed, for "determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, and sending information identifying the server selected transmission path for each of the clients to the respective clients." Instead, the specification discloses that the clients select paths to the server and the clients change those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network.

The '496 Patent – Claims	
	The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing

The '496 Patent – Claims	
	through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client

The '496 Patent – Claims	
	7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a server controller for determining a server selected transmission path for each of the plurality of clients based on the selected transmission paths received from the plurality of clients, as claimed. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the

The '496 Patent – Claims	
	digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers server optimization of paths of clients, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the server's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the server selected path limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform determining server selected paths as claimed.

The '496 Patent – Claims	
	Moreover, to the extent that SIPCO contends that the claimed selection can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a server. In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16. Moreover, the limitation "sending information identifying the server selected transmission path for each of the clients to the respective clients" is indefinite as it cannot be reasonably ascertained what, and to which clients the, "information identifying the server selected transmission path" is sent, and the specification fails to adequately disclose how such function is performed. Moreover, the limitation "sending information identifying the server selected transmission path for each of the clients to the respective clients " renders the claim invalid as indefinite and invalid as the specification lacks a sufficient written description to enable the full scope of the claimed invention. In particular, it is unclear as to whether "information identifying the server selected transmission path for each of the clients" is sent to one client, or to all clients, and the specification lacks sufficient guidance to resolve this ambiguity and lacks an adequate disclosure for such a recitation. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the sending limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform sending as claimed.

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
44. The server of claim 42, wherein the client link entries correspond to the server selected transmission path between the server and the respective client.	This dependent claim is invalid for failing to meet the requirements of 35 U.S.C. § 112(a) and (b) for at least the reasons stated with regard to its base claim. Also, the term "client link entries correspond to" is indefinite because it is unclear what represents an entry and the scope of the claimed correspondence.
45. A first node for use in wireless network system including a plurality of second nodes each including a second node controller implementing a second node process that includes controlling a second node radio modem, receiving and transmitting data packets via said second node radio modem,	This claim is invalid under 35 U.S.C. § 112. The claim is invalid under 35 U.S.C. § 112(b) as this preamble renders the claim indefinite. It is unclear whether an accused infringer or prior art reference needs to include the recited features of the system and second nodes found in the preamble, as the body of the claim does not make clear which features of the system and second nodes are related to the features recited in the body of the claim.
wherein said second node process of each of said second nodes includes initiating a radio transmission path to said first node that is a link to said first node through at least one of the remainder of said plurality of second nodes,	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the '496 patent does not clearly link the claimed functions associated with the initiating limitations to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform initiating as claimed. Additionally, this element is indefinite, as the scope of the second node's actions in initiating cannot be reasonably ascertained.

The '496 Patent – Claims	
said first node comprising: a first node controller and a first node radio modem, said first node controller implementing a first node process that includes controlling said first node radio modem, receiving and transmitting data packets via said first node radio modem, and dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized.	The claim is invalid under 35 U.S.C. § 112(b) as this limitation is indefinite, and the claim is invalid under 35 U.S.C. § 112(a) as the specification lacks a sufficient written description to enable the full scope of the claimed invention. The specification of the Brownrigg family patents, as originally filed, fails to sufficiently disclose a first node process that includes "dynamically updating a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized." Instead, the specification discloses that the clients select paths to the server and the clients optimize those paths. The following portions of the specification support that the clients "optimize" the path (although the citations are made to the '062 patent for simplicity, similar citations can be found in the other Brownrigg patents): "A network client for a wireless communication network of the present invention includes a radio modem capable of communicating with at least one server and at least one additional client, and a digital controller coupled to the radio modem to control the sending and receiving of data packets. The digital controller is further operative to determine an optimal path to at least one server of the wireless network. The optimal path can be either a direct path to the server, or an indirect path to the server through at least one additional client." '062 patent at 5:64-6:6. "If client 18C detects the transmissions of client 18D, it will note that client 18D has less "hops" to the server 16 than does client 18B, and will switch its link from client 18B to client 18D. This process is a part of the 'stabilization' or 'optimization' process of the network 10." '062 patent at 8:59-64. "It will therefore be appreciated that the wireless network system 10 of the present

The '496 Patent – Claims	
	invention is constantly attempting to optimize itself for the "best" data transmission. In the embodiment described herein, this optimization looks solely to the number of hops between the client and the server for the sake of simplicity. However, other factors can also affect the quality of the data transmission. For example, the traffic of data packets through a particular client modem may be large, such that it is better to route the data from neighboring clients through other clients, even though there may be more hops involved with this alternative routing. Also, some radio links may be less robust or may be slower than other links, such that optimization may result in a routing of data around the less robust or slower links, even though it may increase the number of hops to the server 16. Therefore, although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 8:65-9:16. "For example, if the client 18D is a portable computer and is moved around within the wireless network system 10, it will opportunistically change its data communication path as better links become available. For example, if the client 18D is moved close to the client 18B, it may use the client 18B as its link to the server 16. Also, any routing through the client 18D from other clients (such as 18C in this example) will be updated and optimized as the data path for the client 18D changes." '062 patent at 9:26-35. "In the scenario where client 18C realizes it has a better connection to server 16 through the client 18D, the link 30 to client 18B is no longer used, and a new radio link 34 to client 18D is established. This is illustrated in FIG. 1b. Now, clients 18A and 18B remain 1 hop clients, clients 18B remains a 2 hop client, but client 18C is upgraded from a 3 hop client to a 2 hop client. Therefore, the data transmission

The '496 Patent – Claims	
	efficiency of the network has been 'stabilized' or 'optimized.'" '062 patent at 9:59-67. "As noted in this figure, client 7 has made the adjustment to connect to server 26, thereby 'stabilizing' or 'optimizing' the network 26. Also, it should be noted that server 14 has deleted client 7 from its routing table, since client 7 is now using server 26 as its gateway to the Internet. This creates a universe of six nodes, of which are two are servers and of which are four are clients. The average 'hop' distance from a client to a server is 1.5 hops. The remainder FIGS. 26g-26o further illustrate these concepts." '062 patent at 11:5-17. "As will be discussed in greater detail subsequently, the optimization occurs when clients 'hear' transmission from other clients that have a better (i.e. shorter) path to a server." '062 patent at 11:25-28 "In FIG. 2k, the 'stabilization' or 'optimization' process is illustrated. It was previously noted that the client 29 has a non-optimal path to its server. In order to improve this path, client 29 will receive "help" from its neighbors starting with client 7. Client 7 currently has a route to server 14. Client 7 starts randomly probing its neighbors looking for a shorter route to a server. Client 7 finds a shorter route to client 26. Client 7 informs server 14 to drop client 7 from server 14's routing table, and client 7 informs server 26 to add client 7 to its routing table. Since client 29 was 'downstream' from client 07, client 29 dynamically becomes switched to a route to server 26." '062 patent at 11:63-12:7. "In FIG. 2n, client 29 is optimizing its path. Client 29 eliminates 18 from its route by 'leap frogging' past client 18 with the result of the shortest possible 3 hop route to a server. Ultimately, therefore, client 29 route has improved from a 7 hop path through server 14 to the shortest possible 3 hop path to server 26. This result is dynamically

The '496 Patent – Claims	
	accomplished with the efficiencies of client 7, 8, and 18 also improving, and without the need for complex routing algorithms." '062 patent at 12:14-21. In contrast, nothing in the Brownrigg patents discloses a first node process, as claimed, that dynamically updates a second node link tree comprising second node link entries representing each of the plurality of second nodes so that the data packet transmission path to the first node is optimized. Moreover, on October 14, 2008, the patent owner sought claims directed to server optimization. On December 16, 2008, the USPTO did not permit such claims to be added, stating, "The proposed amendment filed 10/14/2008 introduces 'server process' steps into each independent claim and which steps are suggested as being supported via col.5,ln.25-col.6,ln.14, col.9,ln.45-col.12,ln.12 and figures 1 a-2o. The specific passages of the patent cited for support of such server process as introduced by the amendment do not recite the server process receiving the selected transmission path and determining an optimized path based thereon and then sending such optimized path to each of the clients. Instead, col 5, ln.29-38 for example refers to the client choosing a 'best' link to the server; col.5,ln.55-63 refers to the digital controller of the server which allows a client to maintain and upgrade a path to the server; and col.6,ln.2-3 refers to the digital controller of the client determining an optimal path. Likewise, the description in col.9,ln.45-col.12,ln.12 and figures 1 a-2o describe only that a 'tree structure is maintained in the server S, and is transmitted to any client that may request it.' (col.9,ln.47-49). However, the remaining portion of the description continues with an explanation of figures 2a-2o (beginning on col.10,ln.8) where the client requests a route to the server, the server responds (if it is in direct

Exhibit B112 – Invalidity Chart for Brownrigg Family Based on Failure to Comply with 35 U.S.C. § 112

The '496 Patent – Claims	
	path with the server) and adds the client to its routing table in a direct route to the server (col.10,ln.30-40). Second and third clients with indirect routes to the server are described in col.10,ln.41-61, but those clients interact with another client, no description of the server determining an optimized path based on the selection from the client, nor the sending of such optimized path from the server to each of the clients is provided in the recited passages of the specification. As such the proposed amendment to the claims raises new issues." To the extent SIPCO argues that the claim covers a first node that optimizes paths, the specification fails to enable the full scope of the claimed invention. Additionally, this element is indefinite, as the scope of the first node's actions cannot be reasonably ascertained. Moreover, the specification of the '496 patent does not clearly link the claimed functions associated with the dynamically modifying limitation to a disclosed algorithm that performs each of the claimed functions, and the disclosed algorithms do not clearly perform dynamically modifying as claimed. The optimization recitation also renders the claim indefinite because the claim fails to inform, with reasonable certainty, those skilled in the art about the scope of the invention. In particular, it is unclear what would be regarded as "optimal," as such is a subjective standard that varies based on individual preferences. Moreover, to the extent that SIPCO contends that the claimed optimization can involve multiple factors, the specification fails to disclose or enable an optimization algorithm of that employs multiple factors in an optimization process, particularly at a first node as claimed.

The '496 Patent – Claims	
	In fact, the specification effectively admits that a multi-factor algorithm is not disclosed, even for its client-optimization process, stating "although the present preferred embodiment looks at only one single factor in its optimization processes, it will be appreciated by those skilled in the art that multiple factors can be used to stabilize or optimize the wireless network system 10 of the present invention." '062 patent at 9:11-16.

Exhibit P1 – Invalidity Chart for U.S. Patent No. 7,697,492 based on Kahn

The '492 Patent – Claim	Kahn, "*Advances in Packet Radio Technology*", Proceedings of the IEEE, Vol. 66, No. 11, November 1978.
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"Packet radio (PR) is a technology that extends the application of packet switching which evolved for networks of point-to-point communication lines to the domain of broadcast radio. It offers a highly efficient way of using a multiple access radio channel with a potentially large number of mobile subscribers to support computer communication and to provide local distribution of information over a wide geographic area." Kahn Abstract.
a receiver address comprising a scalable address of at least one remote device;	"Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures." Kahn page 1479 "In the point-to-point routing procedure, a packet originating at one part of the network proceeds directly through a series of one or more repeaters until it reaches its final destination. The point-to-point route (which consists of an ordered set of selectors) is first determined by a station which is the only element in the net that knows the current overall system connectivity. Having determined a good point-to-point route, where should the station send the point-to-point routing information? One possibility is for it to distribute the information to the individual repeaters along the point-to-point route. In this case, each succeeding packet would only require some form of source and/or destination identifier but would not have to carry the entire route in its header. Alternatively, the station can send it directly to the digital section of the sender's (or receiver's) packet radio. In this case, each packet originating at that radio could then contain the entire set of selectors in its header." Kahn page 1479.

	"Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules

	belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39.

	"FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source

	Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a command indicator comprising command code;	"SPP is an end-to-end protocol which is used for reliable delivery of network monitor and control packets, such as labelling packets sent to an EPR." Kahn page 1490. "The half duplex operation is keyed to a nominal cycle of packet transmission, acknowledgment receipt, new packet receipt, followed then by its transmission and acknowledgement (see Fig. 7)." Kahn page 1478. "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23 Similarly, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination

	addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	Fig. 8 page 1479. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. a controller associated with a remote device comprising a transceiver configured to send and receive wireless signals, the remote device configured to send a preformatted message comprising the receiver address, a command indicator, and the data value via the transceiver to at least one other remote device.	Fig. 6. "An individual packet radio is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software. The radio and digital sections area connected by a high speed interface (see Fig. 6)." Kahn page 1477. "Normal store-and-forward operation within the network takes

	place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of his packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it." Kahn page 1477. Fig. 8, Kahn page 1479. "For the following discussion, we refer to the operation of an experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." Kahn page 1478. Figure 12, Kahn page 1489. Figure 13, Kahn page 1489. "Each EPR consists of a radio unit, which transmits and receives packets, and a microprocessor-based digital unit, which controls the radio and provides packet header processing (e.g., for routing of packets between nodes). An EPR may operate as a repeater, or may be connected to a user's host computer or terminal, or to a station." Kahn, page 1490.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by

	reference.
a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"An individual packet radio unit is a small piece of electronic equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation." Kahn page 1477. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477. "Each radio has an identifier which we shall call its selector. The selectors play a central role in the network routing and control procedures." Kahn page 1479 Figure 9, Kahn page 1480 Figure 12, Kahn page 1489.
a plurality of controllers associated with each the controller	"An individual packet radio unit is a small piece of electronic

associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	equipment which consists of a radio section and a digital section which controls the radio [26]. The radio section contains the antenna, RF transmitter/receiver, and all signal processing and data detection logic associated with modulation and demodulation. The digital section contains a microprocessor controller plus semiconductor memory for packet buffering and software" Kahn page 1477. "For the following discussion, we refer to the operation of n experimental packet radio, in which a transmitted packet has the structure shown in Fig. 8. It consists of a 48 bit preamble followed by a variable length header (typically 96-144 bits), followed by the text and a 32 bit checksum." To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.

	ETE Header: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

	'252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition

	to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
at least one sensor associated with at least one of the transceivers to detect a condition and output a data signal to the transceiver; and	"1) Network Monitoring and Control: A centralized network management facility (NMF) has been developed for managing and operating the Bay Area experimental testbed. It is somewhat similar to the ARPANET network control center (NCC) [39] in that it collects and displays relevant PRNET status information on a continuous basis. … From the NMF, the network can be debugged, the status of the network can be monitored, tests and measurement experiments can be run, and faults can be detected,

	diagnosed, and isolated." Kahn page 149.
at least one actuator associated with at least one of the transceivers to activate a device.	"2) Debugging the Network: All elements of the packet radio network have been designed to be debugged remotely under test as well as operational conditions. The memory of any packet radio's microprocessor can be remotely examined or altered through the use of the X-RAY debugger by a person at the station. The X-RAY process is routinely used to alter operating parameters in the packet radios (such as power output, frequency, timing, and protocol values) and to examine or alter program code." Kahn page 1495.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "At each repeater, the packet is stored in memory until a positive acknowledgement is received from the next downstream repeater or a time-out occurs."
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "Normal store-and-forward operation within the network takes place as follows. A user generated packet with associated addressing and control information in the packet header is input to the digital section of this packet radio, which adds some network routing and control information and passes the packet to the radio section for transmission to a nearby repeater which is identified within the packet. Upon correct receipt of the packet, the nearby

	repeater processes the header to determine if it should relay the packet, deliver it to an attached device, or discard it. ... The packet with then be relayed from repeater to repeater through the backbone (in a store-and-forward fashion using the procedure described above) until it arrives at the final repeater which broadcasts it directly to the user's packet radio." Kahn page 1477. "1) TIU measurement software-provides sources and sinks of controlled traffic streams; generates and collects pickup packets; received, collects end-device CUMSTATS; and periodically sends collected data to station measurement process. … 2) PRU measurement software-collects subnet CUMSTATS and snapshots; enters local data into pickup packets; and periodically sends collected data to station measurement process. PRU CUMSTATS include counters for packets transmitted, packets received, packets in error, and retransmission histograms. 3) Station measurement software- controls experiments and collects the resulting measurement data." Kahn page 1495. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in Kahn, it would have been obvious to a person ordinary skill in the art to combine and/or modify Kahn with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header

	corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.
