Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	standard interface for the attachment of any number of I/O devices." '650 patent, 7:24-27. "The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
a sensor configured to translate a physical condition into an analog version of the application system input.	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a

	weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10.
51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. To the extent that Plaintiffs contend that this claim limitation is not disclosed

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
54. The system as defined in claim 49, wherein the at least one gateway is connected to the WAN by a network selected from the group consisting of a telecommunications network, private radio-frequency network, and a computer network.	The above contentions for claim 49 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
55. A method of collecting information and providing data services comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
adaptively configuring at least one transmitter with the data translator, wherein the transmitter converts the information signal into a low-power RF signal;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface

	capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.

	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	"Ensuring the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
granting client access to the computer.	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
59. The method of claim 55 wherein the clients access the information using a web browser.	The above contentions for claim 55 are hereby incorporated by reference.

	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘773 patent discloses: “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. ‘773 patent, Figure 2. The ‘817 patent discloses: “FIG. 3 schematically illustrates a communication protocol in accordance with

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
60. A method for controlling an existing control system with a local controller comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
adaptively configuring a data translator disposed between and in communication with both a local controller and a wireless transceiver, wherein the data translator is configured to translate the local controller data stream into an information signal consisting of a transceiver identification code and a concatenation of function codes, the data translator	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

further configured to translate control signals from the wireless transceiver into local controller recognized control signals;	acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer to peer operation. For example, a user application can issue a command of query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices. This allows server workload to be greatly reduced by allowing it to offload work to the data acquisition device which would otherwise have to be performed by the server. In addition, the offload process can be dynamically altered to suit network performance requirements or to circumvent problems due to equipment malfunction." '650 patent, 5:45-57. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely

	attached via cable." '650 patent, 7:9-13. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59. '650 patent, Figure 3. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. "The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45.

	"Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly

	line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.

processing the data into an RF signal;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13.

	"The DA 102 can be programmed to periodically (e.g., once a month) read the meters by issuing commands to the I/O device. The I/O device 206 can continuously read the meters or be powered down to conserve energy. In the preferred embodiment, the I/O device is kept in a low power state and activated under control of the DA 102. When I/O device is activated, it reads all of the meters 502, 504, 506 and transfers the measured data to DA 102." ''650 patent, 9:37-45. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 requests meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer meter data from all of the meters to its primary cache 202." '650 patent, 10:6-12.
transmitting the RF signal to a gateway;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." 	202." '650 patent, 10:6-12. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. "Ensuring that the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,963,650

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference. "Ensuring that the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent, 6:60-63. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located

	anywhere to be provided to a single APP 112." '650 patent, 10:54-57. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

The '732 Patent – Claim	U.S. Patent No. 5,963,650
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. "Referring to FIG. 1, this figure shows an overview block diagram of the

	system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "Another feature shown by the foregoing figures is the shared hierarchical structure of the system. In particular, the DAs 102 may be shared by multiple APPs 112. … Likewise, APPs 112 may reside on a single DCS, or be distributed over a hierarchical network of computers." '650 patent, 8:33-44. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59. '650 patent, Figure 3.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

transceiver, and transceiver identification information associated with the transceiver making retransmission;	"The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.

with one or more retransmit- ting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4.

	"I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204. For ease of discussion, RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and the I/O interface connector 204 are shown as separate components. However, the preferred embodiment envisions these components as a single integrated component." '650 patent, 7:1-10. '650 patent, Figure 2.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the

	uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with

	the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35.

	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to

	implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650

	patent, 3:1-15.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "Ensuring that the appropriate DA 102 communicates with the appropriate APP 112 is accomplished via any suitable identification protocol for communication devices." '650 patent 6:60-63. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice

	the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204. For ease of discussion, RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and the I/O interface connector 204 are shown as separate components. However, the preferred embodiment envisions these components as a single integrated component." '650 patent, 7:1-10. '650 patent, Figure 2.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires

	data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for

	performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31, further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	The above contentions for claim 31 are hereby incorporated by reference. "In systems which cover wide geographical or nationwide areas, many data collection systems may be linked together in a hierarchical or distributed server network, thereby allowing applications located on other computers or networks to access the data from a particular data acquisition device. By caching the data at the data collection system, substantial improvements in the overall system performance can be achieved. When global networks, such as the Internet, are used to access data acquisition devices worldwide, the use of the dual cache system described above becomes even more advantageous." '650 patent, 5:12-22. "Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple

	processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1. "Another feature shown by the foregoing figures is the shared hierarchical structure of the system. In particular, the DAs 102 may be shared by multiple APPs 112. … Likewise, APPs 112 may reside on a single DCS, or be distributed over a hierarchical network of computers." '650 patent, 8:33-44. "FIG. 3 illustrates another technique used by the DA 102 to reduce power consumption. This technique uses peer to peer data transfers to minimize the power required by the RF transceiver 210 by reducing the transmission distance required to contact the DCS 100. As shown in this figure, a remotely located DAs 102 (Numbers 1, 2 and 3) transfer data to DA 102 (number 4), which in turn transfers the data to DA 102 (number 5) which then transfers the data to DCS 100. This configuration allows a DCS 100 to receive data from a DA 102 which may be too remotely located to contact it at a low power setting. Those skilled in the art will recognize that the configuration of DAs 102 shown in this figure can be rearranged such that a variety of redundant data paths exist for transfer of data from any particular DA 102 to the DCS 100." '650 patent, 8:45-59. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '773 patent discloses: "Providing Gateway Services to the individual Minion devices means that all

	Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a

	weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. "The system provides a remotely located data acquisition device which may be

	a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26.

	'650 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses:

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 5,963,650

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the

	cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,963,650

The '780 Patent – Claim	U.S. Patent No. 5,963,650
1. In a system comprising a plurality of wireless devices, a device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an

	I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,963,650

	be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,963,650

	and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The contentions for claim 1 are hereby incorporated by reference. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security

	sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O

	device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. '650 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by

	monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,963,650

	3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The contentions for claim 1 are hereby incorporated by reference. '650 patent, Figure 1. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for

	numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102

	through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 5,963,650

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device

	and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The contentions for claim 1 are hereby incorporated by reference. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The

	detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be

	used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The contentions for claim 1 are hereby incorporated by reference. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both

	point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The contentions for claim 1 are hereby incorporated by reference. "Anther technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a lower power state until activated by a signal demanding a data reading. When the signal is received full power is applied to the data acquisition device (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in sleep state until the next measurement is required." '650 patent, 1:63-2:4. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for

	numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the

	processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Primary cache 202 is used to store data and/or commands to or from the I/O device 206. By using the primary cache 202, a query from DCS 100 can be satisfied without activating I/O device 206 so long as the required data is in the cache 202. …In the preferred embodiment, a complete wireless networking protocol is stored in DA 102 which is capable of supporting both point to point and point to multi-point communications. In addition source routing of messages is included in the stored program to allow the transmission distance of DA 102 to be extended by routing messages across multiple DAs 102." '650. 7:28-35. '650 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S.

	Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports

	debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message

	with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The contentions for claim 1 are hereby incorporated by reference. '650 patent, Figure 1.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,908,842 based on U.S. Patent No. 5,963,650

The '842 Patent – Claim	U.S. Patent No. 5,963,650
1. A device for communicating information, the device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCS with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCS with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
an interface circuit for communicating with a central location; and	"In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,908,842 based on U.S. Patent No. 5,963,650

	vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. '650 patent, Figure 1.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1
7. The device of claim 1, wherein the controller is further	The contentions for claim 1 are hereby incorporated by reference.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,908,842 based on U.S. Patent No. 5,963,650

configured to communicate a transceiver identification code to the central location via the interface circuit.	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The contentions for claim 1 are hereby incorporated by reference. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
16. A device for communicating information, the device comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCS with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract.
a processor; and	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the

Exhibit P6 – Invalidity Chart for U.S. Patent No. 8,908,842 based on U.S. Patent No. 5,963,650

	primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
a memory, the memory comprising logical instructions that when executed by the processor are configured to cause the device to:	"Referring to FIG. 1, this figure shows an overview block diagram of the system. The data collection system 100 (hereinafter, "DCS 100") in the preferred embodiment is a server, but may be any suitable system such as a mainframe computer, personal computer, specialized hardware, etc. For ease of discussion, the term processor 104 will be used to describe the primary data processing circuitry. However, processor 104 can be a processor, multiple processors, a microprocessor, an intelligent microcontroller, etc. DCS 100 controls data collection between user applications 112 (hereinafter "APP 112") and data acquisition devices 102 (hereinafter "DA 102")." '650 patent, 5:58-6:2. '650 patent, Figure 1.
wirelessly transmit a signal comprising instruction data for delivery to a network of addressable low-power transceivers;	"The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to

	work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

The '893 Patent – Claim	U.S. Patent No. 5,963,650
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer

	to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station, irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can

	be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers,

	which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet."

	'252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a command indicator comprising a command code;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for

	numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42.
at least one data value comprising a scalable message; and	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed.

	Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. an error detector comprising a redundancy check error detector; and	"A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment,

	the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages.	"Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer the meter data from all of the meters to its primary cache 202." '650 patent, 10:7-12.
2. The system of claim 1, wherein the plurality of transceivers further comprise at least one integrated transceiver, wherein the integrated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers; and	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204. For ease of discussion, RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and the I/O interface connector 204 are shown as separate components. However, the preferred embodiment envisions these components as a single integrated component. … For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102, can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:1-16.
a sensor detecting a condition and outputting a sensed data signal to the transceiver.	"FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214,

	and I/O interface connector 204. For ease of discussion, RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and the I/O interface connector 204 are shown as separate components. However, the preferred embodiment envisions these components as a single integrated component. … For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102, can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:1-16.
3. The system of claim 2, wherein the at least one integrated transceiver receives the preformatted command message requesting sensed data, confirms the receiver address as its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet, wherein the packets are equal to the number of segments.	The above contentions for claim 2 are hereby incorporated by reference. "Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer the meter data from all of the meters to its primary cache 202." '650 patent, 10:7-12. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.

10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference.
one of the plurality of transceivers;	"The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42.

	"User applications may be any activity suitable for a system which requires data from a wide area to be transmitted to a central control point. For example, in a vineyard operation, each DA 112 could be a sensor device such as a weather station or ground water monitor, a unit of active equipment such as fertilizing or irrigation equipment, etc., or a combination of any of these devices. Each APP 112 can be used for a specific purpose such as water monitoring, fertilizing, etc." '650 patent, 6:2-10. "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26.
a sensor detecting a second condition and outputting a sensed data signal to the transceiver; and	"Those skilled in the art will recognize that minor changes can be made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O

	device to transfer the meter data from all of the meters to its primary cache 202." '650 patent, 10:7-12.
an actuator controlling a third condition and receiving control signals from the transceiver.	"Another technique used to reduce battery power consumption is to place the data acquisition device in a "sleep" mode, whereby the device normally rests in a low power state until activated by a signal demanding a data reading. When the signal is received, full power is applied to the data acquisition device, the data (e.g. meter reading) is read, the data is transmitted to the data collection system, and the data acquisition device is placed back in the sleep state until the next measurement is required." '650 patent, 1:63-2:4.
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"A customizable data acquisition device (DA) and data collection system (DCS). The DA is remotely located for attachment to a variety of I/O devices, and uses an RF transceiver with a primary cache. A centrally located or mobile DCC with a secondary cache communicates with one or more DA's and stores DA data in the secondary cache." '650 patent Abstract "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and

	irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or unit of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-29. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "I/O device 206 can be any suitable user designed unit required for a particular function. For example, it can be a weather station,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	irrigation equipment, manufacturing equipment, security system, etc. For ease of illustration, this figure illustrates the I/O device 206 as part of the DA 102. However, in practice the DA 102 can be attached directly to an I/O device 206 or it can be remotely attached via cable." '650 patent, 7:9-13. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202,

	program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.

	ETE Header: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	‘252 patent, Figure 25. “The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll.” ‘252 patent, 39:28-43. ‘252 patent, Figure 31. “For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition

	to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing:

	Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3.

a command indicator comprising a command code;	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28.

	"A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host

	computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once

	every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. '650 patent, Figure 3. "The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses.

	Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector;	"A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment, the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14.
wherein the controller sends preformatted command messages via	"Those skilled in the art will recognize that minor changes can be

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

the controller transceiver, and the plurality of transceivers send preformatted response messages; and	made to the foregoing method. For example, a meter reading may be initiated by the first APP 112 to request data for a billing period. When the APP 112 request meter data, the DCS 100 sends a command to the DA 102 which in turn commands the I/O device to transfer the meter data from all of the meters to its primary cache 202." '650 patent, 10:7-12.
wherein at least one of the plurality of transceivers further sends preformatted emergency messages.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module,

	or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
18. The system of claim 17, wherein the controller maintains periods of silence by not sending the preformatted command messages during predetermined time periods; and	The above contentions for claim 17 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault

	messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
wherein the at least one of the plurality of transceivers detects a period of silence and sends the preformatted emergency message during the period of silence.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. 	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules

	belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39.

	"FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source

	Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a sender address comprising an unique address of the sender;	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202,

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
a command indicator comprising a command code;	"The foregoing examples concentrated on utility meter data collection as a method of illustrating general data acquisition and power conservation concerns. However, those skilled in the art will recognize that a variety of applications exist for the collection of data, including industrial, manufacturing, financial, security and agriculture, to name just a few. Industrial processes may require monitoring of materials as they are processed. Manufacturing plants can be designed to control activity and parts delivery on an long assembly line. Remote devices such as ATMs can be monitored for maintenance and security. Security systems are needed for monitoring homes and businesses. Agricultural uses include control systems for fertilization and irrigation. As can be seen, data acquisition systems an be used for numerous purposes." '650 patent, 3:1-15. "The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a

	detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "The system provides a remotely located data acquisition device which may be a sensor or a piece of equipment which performs a specific active function, such as irrigation in agricultural environments or control of a manufacturing assembly line." '650 patent, 4:25-28. "A significant advantage of the program storage is that in combination with the uniform I/O connector interface, it allows a single interchangeable RF transceiver type to be customized to work with a wide variety of devices, such as weather or security sensors, agricultural devices, manufacturing equipment, etc." '650 patent, 5:37-42. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.

Exhibit P6 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 5,963,650

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 7,027,773 ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

	Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command

	station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. "As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.
a scalable data value comprising a scalable message; and	"The present invention solves the foregoing problems by providing a data acquisition device and a data collection system. The data acquisition device includes a primary cache, a detachable RF transceiver, and a user supplied sensor device. The data collection system includes a secondary cache. The detachable RF transceiver has a programmable controller and an I/O interface capable of attaching to a variety of user supplied sensor devices….Each data acquisition device is capable of peer to peer communication such that data acquisition devices outside of the range of the data collection device can communicate with the data collection device through other data acquisition devices." '650 patent, 3:27-47. "FIG. 2 provides a more detailed block diagram of the DA 102. The DA 102 includes RF Transceiver 210, primary cache 202, program storage 208, microprocessor 212, microcontroller 214, and I/O interface connector 204." '650 patent, 7:1-4. '650 patent, Figure 2.

	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '650 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '650 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules

	belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector that is a redundancy check error detector; and	"A unique feature of the preferred embodiment is its use of pincodes to encrypt the CRC data. In the preferred embodiment, the networks 402, 406 use pincodes 404, 408 to encrypt the cyclic redundancy check (CRC) data. CRC data is well known in the art." '650, 9:9-14.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"As shown above, in FIG. 3, the DA 102 is also designed to function as a node in a mesh of RF-communicating devices, relaying information received from I/O devices 206 (which may be sensors or active devices), across the network in a daisy-chain form. Since each node is individually addressable, messages can be routed from source to destination via any number of nodes, without limiting the coverage area." '650 patent, 11:47-54.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

The '492 Patent – Claim	U.S. Patent No. 7,027,773
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a receiver address comprising a scalable address of at least one remote device;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates are feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended

	receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." '’773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules

	belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39.

	"FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. 	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host

	computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once

	every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates are feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more

	commercialized and proposing extensions for IP addressing.
a controller associated with a remote device comprising a transceiver configured to send and receive wireless signals, the remote device configured to send a preformatted message comprising the receiver address, a command indicator, and the data value via the transceiver to at least one other remote device.	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33.

	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by reference.
a plurality of transceivers each having a unique address, the	"It is an object of this invention to provide a low cost, multi-node

transceiver being one of the plurality of transceivers;	system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex™ network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm."

	'773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive

	the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	“The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a

	subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. 3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute

	the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10"27-33 and 13:6-19. '773 patent, Figures 9A and 9C.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10:27-33 and 13:6-19. '773 patent, Figures 9A and 9C.

	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers

	that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and

	receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network

	service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for

	Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
6. The system of claim 1, wherein each remote device is adapted to transmit and receive radio frequency transmissions to and from at least one other transceiver.	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system

	having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex™ network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and

	(4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
8. A method of communicating command and sensed data between remote wireless devices, the method comprising:	“It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-

In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example,

	Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than

	they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition

	device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the

	information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet."

	'252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a

which the duplicate message originated.	subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or

	explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for

	controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example,

	Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets:

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31.

	"For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present,

	resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375,

	October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard

	fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." '’773 patent, 14:5-20.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	'773 patent, Figure 1 and 2.
a transceiver configured to send and receive wireless communications; and	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex^{TM} network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: i. the serial number of the Minion device generating the message (originator);

	j. the serial number of the Minion device transmitting the message (sender); k. the serial number of the Minion device intended to receive the message (recipient); l. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator	“The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference

comprising a command code, a data value comprising a scalable message.	frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates are feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the

	device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." ‘773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the ‘217 patent"), U.S. Patent No. 5,907,491 ("the ‘491 patent"), U.S. Patent No. 5,963,650 ("the ‘650 patent"), U.S. Patent No. 6,100,817 ("the ‘817 patent"), U.S. Patent No. 5,874,903 ("the

	'903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header.

	ETE Header: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "Each Minion device would include an interface to a sensor

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	related to a measurable phenomenon located in close proximity to the Minion device itself." '773 patent, 41:46-49.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation

	systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet

	network." '773 patent; 22:13-19.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as

	determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." ‘773 patent; 22:13-19.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." ‘773 patent, 17:57-60. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the ‘217

	patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNetTM Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g.,

	wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex^{TM} network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-

	60. "As shown in FIG. 4, a gateway Minion device 120 comprises a μMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the μMinion devices or receive data from the μMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: m. the serial number of the Minion device generating the message (originator); n. the serial number of the Minion device transmitting the message (sender); o. the serial number of the Minion device intended to receive the message (recipient); p. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared

	memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33. “The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission.” ‘’773 patent, 14:5-20. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. “The Data portion of a MinionNet network Standard Message

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most

	notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates are feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device

	and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter

	memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent

	week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: “FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers.” ‘252 patent, 38:34-43. ‘252 patent, Figure 25. “The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "Each Minion device would include an interface to a sensor related to a measurable phenomenon located in close proximity to the Minion device itself." '773 patent, 41:46-49.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10:27-33 and 13:6-19. '773 patent, Figures 9A and 9C. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data between remote wireless communication devices, the wireless communication device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system

	having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a transceiver configured to send and receive wireless communications; and	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or

	wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex™ network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60.

	"As shown in FIG. 4, a gateway Minion device 120 comprises a μMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the μMinion devices or receive data from the μMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: q. the serial number of the Minion device generating the message (originator); r. the serial number of the Minion device transmitting the message (sender); s. the serial number of the Minion device intended to receive the message (recipient); t. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these

	serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable message.	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23.

	"A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates are feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information

	originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. "*A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

Exhibit P7 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 7,027,773

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

transceiver, and transceiver identification information associated with the transceiver making retransmission; and	with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless

	communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	with regard to FIG. 7." '773 patent, 7:18-26.
5. A system for monitoring remote devices, comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"Sensors – Temperature, barometric pressure (for weather or altitude), magnetic flux, (for metal detection, change in attitude or compass), accelerometers (for motion, attitude change), motion or shock detectors, etc. may be connected." '773 patent, 49:16-19. "Meter Reading—Minion devices could be built in the form factor of a modem for inclusion in various advanced meter designs to provide remote meter reading capability. Similar opportunities exist for water and gas meters. The system would also provide remote meter reading capability for electric, gas and water, as well as numerous generation, production and distribution

	applications, such as pipelines." '773 patent, 49:33-39. "Machine Status – Minion devices could be installed to provide inventory and coin-box status." '773 patent, 50:46-47.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "The basic µMinion devices may be used as stand-alone devices which perform the prescribed network functions, or they may be connected to or embedded in external equipment or devices. For example: …Building and Factory Management and Controls--Heating, Ventilation, Air Conditioning and Refrigeration equipment and their controls, including thermostats, humidity sensors, motion detectors, occupancy sensors, exit signs, door locks, lighting fixtures and controls, emergency alarms, signaling devices, security devices." '773 patent 48:50-49:2. "The µMinion is a low-cost, intelligent two-way data radio. It participates as a member of a self-organizing network of functionally identical nodes. Each µMinion can originate and receive data messages, and can act as an intermediary in forwarding messages on behalf of other µMinions." '773 patent, 51:60-64. "Messages which are transmitted between Minion devices will each contain a

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	“The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging.” ‘773 patent, 4:44-46. ‘773 patent, Figure 1 and 2. “The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node.” ‘773 patent, 2:26-34.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal	“It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of

and transmitter identification information to a computer on the WAN; and	environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located	"Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52.

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

device.	“This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm.” ‘773 patent, 7:6-17.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. “As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7.” ‘773 patent, 7:18-26.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43.
9. A system for controlling a remote device comprising:	“Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services,

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23.
a target remote device having an actuator to be controlled;	“Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	“Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source.” ‘773 patent, 6:48-52. “This is accomplished by making a small percentage of the Minion devices in

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	"As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. '773 patent, Figure 4.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figures 1 and 2 and 4.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "A number of major market areas have been identified most notably utility

	monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data

	storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. remotely located device, said computer integrated with a wide area network (WAN);	off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
a plurality of non-earth orbiting transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand

configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17.

	"Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: e. the serial number of the Minion device generating the message (originator); f. the serial number of the Minion device transmitting the message (sender); g. the serial number of the Minion device intended to receive the message (recipient); h. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain

Exhibit P7– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 7,027,773

	space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

	"As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 12 are hereby incorporated by reference. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

The '692 Patent – Claim	U.S. Patent No. 7,027,773
1. A system for remote data collection, assembly, and storage comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of

	environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand

	off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in

	the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options

	and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
a plurality of relatively low-power radio-frequency	"It is an object of this invention to provide a low cost, multi-node system which

3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59.

	"The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate

	feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: i. the serial number of the Minion device generating the message (originator); j. the serial number of the Minion device transmitting the message (sender); k. the serial number of the Minion device intended to receive the message

	(recipient); l. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. “For example, the MinionNet network may be used as a geolocation network as described below. In this environment, this is accomplished by making a small percentage of the Minion devices in the field act as geoMinion devices 130 illustrated in block diagram form in FIG. 3. These geoMinion devices 130 interface with the global positioning systems (GPS) already in place to act as anchor points for locating other Minion devices.” ‘773 patent, 6:40-48. ‘773 patent, Figure 3. “Sensors – Temperature, barometric pressure (for weather or altitude),

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	magnetic flux (for metal detection, change in attitude or compass), accelerometers (for motion, attitude change), motion or shock detectors, etc. may be connected." '773 patent, 49:17-19. "Meter Reading – Minion devices could be built in the form factor of a modem for inclusion in various advanced meter designs to provide remote meter reading capability." '773 patent, 49:32-35.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "In another form, the invention is a message having a protocol which permits the message to be successively transmitted by a wireless network of transceiver nodes employing node-to-node messaging. A message including data is sent from a first node originating via one or more intermediate nodes to a last node designated by the first node as the destination of the message. The message comprises: data bits corresponding to the data; originating bits identifying the first node from which the message originates; destination bits identifying the last node to which the message is destined; transmitting bits identifying the current node transmitting the message; and receiving bits identifying the next node intended to receive the message currently being transmitted." '773 patent, 2: 52-65. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information,

	time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." ‘817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." ‘773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." ‘773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of

	which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the

	nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. '773 patent, Figure 4. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below

	with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
8. The system as defined in claim 7, wherein the computer is further configured to respond to	The above contentions for claim 7 are hereby incorporated by reference.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	"As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." 	patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will be described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those

	serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." ‘773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." ‘773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: q. the serial number of the Minion device generating the message (originator); r. the serial number of the Minion device transmitting the message (sender); s. the serial number of the Minion device intended to receive the message (recipient); t. the serial number of the Minion device intended as the final destination

	of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
translating the data in the RF signal into a network transfer protocol;	“The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging.” ‘773 patent, 4:44-46. ‘773 patent, Figure 1 and 2. “It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system

	via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. '773 patent, Figure 2.
sending the translated data to a computer, wherein	"Providing Gateway Services to the individual Minion devices means that all

"Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: y. the serial number of the Minion device generating the message (originator); z. the serial number of the Minion device transmitting the message (sender); aa. the serial number of the Minion device intended to receive the message (recipient); bb. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	"Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
at least one wireless transmitter configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a low-power radio-frequency (RF) signal;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops'

	to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information,

	time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." ‘773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." ‘773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: cc. the serial number of the Minion device generating the message (originator); dd. the serial number of the Minion device transmitting the message (sender); ee. the serial number of the Minion device intended to receive the message (recipient); ff. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." ‘773 patent, 18:14-40.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the	The above contentions for claim 32 are hereby incorporated by reference.

transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	"This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol

	congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to

	implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
at least one gateway connected to the WAN configured to receive and translate the at least one control signal; said gateway further configured to transmit a radio-frequency (RF) signal containing the control signal and destination information;	"The MinionNet[TM] Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "It is an object of this invention to provide a low cost, multi-node system which

	hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56.

	"The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.

	"Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a μMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the μMinion devices or receive data from the μMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: oo. the serial number of the Minion device generating the message (originator); pp. the serial number of the Minion device transmitting the message (sender); qq. the serial number of the Minion device intended to receive the message (recipient); rr. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

	"Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"In another form, the invention is a message having a protocol which permits the message to be successively transmitted by a wireless network of transceiver nodes employing node-to-node messaging. A message including data is sent from a first node originating via one or more intermediate nodes to a last node designated by the first node as the destination of the message. The message comprises: data bits corresponding to the data; originating bits identifying the first node from which the message originates; destination bits identifying the last node to which the message is destined; transmitting bits identifying the current node transmitting the message; and receiving bits identifying the next node intended to receive the message currently being transmitted." '773 patent, 2: 52-65. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver

	for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." ‘817 patent, 7:61-66.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." ‘773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in

	the world and can be directed to any Minion device." '773 patent, 7:39-43.
47. The system defined in claim 42, wherein the WAN is the Internet.	The above contentions for claim 42 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses:

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	"When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based

	network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a

	header area and a data area. The header area will contain the following bit fields: ss. the serial number of the Minion device generating the message (originator); tt. the serial number of the Minion device transmitting the message (sender); uu. the serial number of the Minion device intended to receive the message (recipient); vv. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command.…" '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access.…"

51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in

	the world and can be directed to any Minion device." ‘773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23. Burchfiel discloses: “When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway

	function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in

	the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d.. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54. "Additional objects includes providing a system a method which:

	"A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.
granting client access to the computer.	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43.

56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. “This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm.” ‘773 patent, 7:6-17. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23. Burchfiel discloses: “When some other network is present, it is important to provide connections

	between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 55 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249.

	Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." ‘773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." ‘773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message

	(sender); c. the serial number of the Minion device intended to receive the message (recipient); d.. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54. “Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control,

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
remotely collecting data from the at least one relatively low-powered radio-frequency (RF) transceiver integrated with the data translator;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which

	permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway

	Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	header area and a data area. The header area will contain the following bit fields: a.. the serial number of the Minion device generating the message (originator); b.. the serial number of the Minion device transmitting the message (sender); c.. the serial number of the Minion device intended to receive the message (recipient); d.. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
transmitting the RF control signal;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless

	data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will ne described below." '773 patent, 4:60-63. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-51. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned

	during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a.. the serial number of the Minion device generating the message (originator); b.. the serial number of the Minion device transmitting the message (sender); c.. the serial number of the Minion device intended to receive the message (recipient);

	d.. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54. “Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33.

'773 patent, 6:28-33. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249.

	Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses:

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 7,027,773

	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses:

	"The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112.

	However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

The '732 Patent – Claim	U.S. Patent No. 7,027,773
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a

	plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet

	gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57. The '817 patent discloses: "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically inter- faced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning

type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	encountered during transmission." ''773 patent, 14:5-20. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm."

	'773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as

	cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for

	performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	'773 patent, Figure 1 and 2.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the

	message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: e. the serial number of the Minion device generating the message (originator); f. the serial number of the Minion device transmitting the message (sender); g. the serial number of the Minion device intended to receive the message (recipient); h. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time,

	history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	“The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging.” ‘773 patent, 4:44-46. ‘773 patent, Figure 1 and 2. “The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node.” ‘773 patent, 2:26-34.
a data controller operatively coupled to the transceiver and the sensor, the data controller configured to control the transceiver and receive data from the sensor, the data controller configured to format a data packet for transmission via the	“The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver

transceiver, the data packet comprising data representative of data sensed with the sensor.	to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the

	protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
14. The device of claim 13, wherein the data controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 13 are hereby incorporated by reference. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control."

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	'817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. The above contentions for claim 13 are hereby incorporated by reference. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.

19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the command.	The above contentions for claim 13 are hereby incorporated by reference. “Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19. “The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned

	during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the ‘217 patent"), U.S. Patent No. 5,907,491 ("the ‘491 patent"), U.S. Patent No. 5,963,650 ("the ‘650 patent"), U.S. Patent No. 6,100,817 ("the ‘817 patent"), U.S. Patent No. 5,874,903 ("the ‘903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the

	commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor

	4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to

	other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion

	devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: i. the serial number of the Minion device generating the message (originator); j. the serial number of the Minion device transmitting the message (sender); k. the serial number of the Minion device intended to receive the message (recipient); l. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.

a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
wherein the controller is configured to receive control signals from a data packet and based on the	"Additional objects includes providing a system a method which: ***

control signals send instructions to an actuator to implement a command.	shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated.” Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: “The “function fields” provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process.” Burchfiel page 247. “A level-3 debugging protocol has been defined which supports debugging of remote PRU’s from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting “mousetraps” which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure.” Burchfiel page 248.

	U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control."

	'817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31**,** further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	The above contentions for claim 31 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." ‘773 patent; 22:13-19
33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." ‘773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

	Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 7,027,773

35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: “From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated.” Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: “PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator.” Jubin page 23. “A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging.” Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: “The “function fields” provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process.” Burchfiel page 247. “A level-3 debugging protocol has been defined which supports debugging of remote PRU’s from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting “mousetraps” which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure.” Burchfiel page 248. U.S. Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: “Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements.” ‘903, 4:23-31.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

The '780 Patent – Claim	U.S. Patent No. 7,027,773
1. In a system comprising a plurality of wireless devices, a device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

	having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and

	(4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion.

	Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	“The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission.” ‘’773 patent, 14:5-20.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node." '773 patent, 2:26-34. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

	of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. Additional objects includes providing a system a method which:

	*** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33. “Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." ‘773 patent, 7:39-43. “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

	of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the

	measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response	The above contentions for claim 1 are hereby incorporated by reference.

to the function code, implement a function.	Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access….” ‘773 patent, 1:59-2:23. “A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management.” ‘773 patent, 6:28-33. “The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission.” ‘’773 patent, 14:5-20.

	"Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off,

	and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the

	command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect

Exhibit P7– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 7,027,773

	errors encountered during transmission." ''773 patent, 14:5-20.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.

	U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought

	of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more

	of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the

	measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	The above contentions for claim 1 are hereby incorporated by reference.

	"The devices used by the MinionNet network 100 are generally referred to as Minion devices and are actually extremely inexpensive two-way radios, such as a transceiver as will be described below." '217 patent, 4:60-63. '217 patent, Figure 1.

Exhibit P7– Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 7,027,773

The '842 Patent – Claim	U.S. Patent No. 7,027,773
1. A device for communicating information, the device comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120

Exhibit P7– Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 7,027,773

	illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
an interface circuit for communicating with a central location; and	"This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "As shown in FIG. 4, a gateway Minion device 120 comprises a

	µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26.

	"Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.

7. The device of claim 1, wherein the controller is further configured to communicate a transceiver identification code to the central location via the interface circuit.	The above contentions for claim 1 are hereby incorporated by reference. “Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique.” ‘773 patent, 17:57-60. “As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7.” ‘773 patent, 7:18-26. “Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion.

	Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes." '773 patent, 52:40-54.
9. The device of claim 1, wherein transmitted and received signals further comprise a field configured to indicate a destination device for a subsequent transmission path to follow.	The above contentions for claim 1 are hereby incorporated by reference. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options

Exhibit P7– Invalidity Chart for U.S. Patent No. 8.908,842 based on U.S. Patent No. 7,027,773

	and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: e. the serial number of the Minion device generating the message (originator); f. the serial number of the Minion device transmitting the message (sender); g. the serial number of the Minion device intended to receive the message (recipient); h. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command…." '773 patent, 18:14-40. "Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information,

the controller further configured to receive one or more data signals from the central location via the interface circuit and communicate information contained within the signals to the remote device.	"Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "Providing Gateway Services to the individual Minion devices means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information

	originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

The '893 Patent – Claim	U.S. Patent No. 7,027,773
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.™ devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "The MinionNet™ Network 100 as illustrated in FIGS. 1 and 2 is a wireless data network characterized by short-range device-to-device messaging." '773 patent, 4:44-46. '773 patent, Figure 1 and 2.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted	"It is an object of this invention to provide a low cost, multi-node system which hands off messages from node-to-node; a system of nodes which hands off messages and provides implicit and/or explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as

messages;	"Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17. "Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set

	of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a μMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the μMinion devices or receive data from the μMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: a. the serial number of the Minion device generating the message (originator); b. the serial number of the Minion device transmitting the message (sender); c. the serial number of the Minion device intended to receive the message (recipient); d. the serial number of the Minion device intended as the final destination of this message (destination); … j. a type code that controls the interpretation of the data portion.

	Type codes include but are not limited to the following: position, time, history, request/response, command….” '773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” '773 patent, 52:40-54.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	“The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node.” '773 patent, 2:26-34. “Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source.” '773 patent, 6:48-52.

	"Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. "Providing Gateway Services to the individual Minion devices

	means that all Minion devices effectively become part of the Internet as shown in FIG. 2. Status enquiries and data messages can originate at any Internet workstation in the world and can be directed to any Minion device." '773 patent, 7:39-43. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the

	device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …

	Routing Header: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are

	supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network

	service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that

	uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

a command indicator comprising a command code;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." ‘773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the ‘217 patent"), U.S. Patent No. 5,907,491 ("the ‘491 patent"), U.S.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports

	debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the

	preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the

	device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …

	Routing Header: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are

	supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network

	service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that

	uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages.	"FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10"27-33 and 13:6-19.
2. The system of claim 1, wherein the plurality of transceivers further comprise at least one integrated transceiver, wherein the integrated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference. "Each Minion device would include an interface to a sensor related to a measurable phenomenon located in close proximity to the Minion device itself." '773 patent, 41:46-49.
one of the plurality of transceivers; and	"Each Minion device would include an interface to a sensor related to a measurable phenomenon located in close proximity to the Minion device itself." '773 patent, 41:46-49.

a sensor detecting a condition and outputting a sensed data signal to the transceiver.	"Each Minion device would include an interface to a sensor related to a measurable phenomenon located in close proximity to the Minion device itself." '773 patent, 41:46-49.
3. The system of claim 2, wherein the at least one integrated transceiver receives the preformatted command message requesting sensed data, confirms the receiver address as its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet, wherein the packets are equal to the number of segments.	"FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10"27-33 and 13:6-19. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of

	the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used

	for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery

	subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
10. The system of claim 1, wherein the plurality of transceivers further comprise at least one actuated transceiver, wherein the actuated transceiver comprises:	The above contentions for claim 1 are hereby incorporated by reference. Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-

wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	explicit acknowledgment of the hand off; a flexible, adaptable multi-node system which is applicable in a plurality of environments and for a plurality of uses; a multi-node system having stationary nodes and mobile nodes (known as "Minion.TM. devices") the position of which can be determined by the stationary nodes; a multi-node system which permits nodes to communicate with a wide area network or a global positioning system via a selected number of nodes; a multi-node system which operates multiple applications at each node; and a multi-node system which interfaces with a plurality of "gateways", e.g., wide area network (WAN) connections to other communications networks, whether wired or not, such as telephone or CATV or wireless, or satellite or terrestrial." '773 patent, 1:43-59. "Messages are automatically routed through multiple device-to-device 'hops' to provide robust area coverage, redundancy, noise immunity and dynamic routing and reconfiguration." '773 patent, 4:53-56. "This is accomplished by making a small percentage of the Minion devices in the field act as gateway Minion devices 120 illustrated in block diagram form in FIG. 4. These gateway Minion devices 120 act as concentrators for messages bound to and emanating from the centralized supervisory components of the nationwide MinionNet network. The actual wide area connectivity of a gateway Minion device may be provided by a terrestrial wide area wireless data network such as the Bell South Wireless Data Mobitex.RTM. network, a cellular based network using CDPD, or a satellite-based data network such as Orbcomm." '773 patent, 7:6-17.

	"Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits." '773 patent, 14:11-17. "Each Minion device is assigned a unique serial number which is installed during manufacture that identifies that particular Minion device so that each Minion device is unique." '773 patent, 17:57-60. "As shown in FIG. 4, a gateway Minion device 120 comprises a µMinion device 110 configured to interface with a wide area network (WAN) interface 400. The WAN interface 400 would be in contact, either directly or wireless communication with other stations which would provide data to the µMinion devices or receive data from the µMinion devices. The power supply options and power control of the gateway Minion device 120 will be described below with regard to FIG. 7." '773 patent, 7:18-26. "Messages which are transmitted between Minion devices will each contain a header area and a data area. The header area will contain the following bit fields: e. the serial number of the Minion device generating the message (originator); f. the serial number of the Minion device transmitting the message (sender); g. the serial number of the Minion device intended to receive the message (recipient); h. the serial number of the Minion device intended as the

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	final destination of this message (destination); … j. a type code that controls the interpretation of the data portion. Type codes include but are not limited to the following: position, time, history, request/response, command….” ‘773 patent, 18:14-40. “Each Minion has a unique 32-bit serial number assigned during manufacture. This gives over four billion numbers, although number reuse is not as big an issue in this environment as it is in some others. Each message will contain space for four of these serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes.” ‘773 patent, 52:40-54.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	“The system comprises a plurality of at least three nodes. Each node hands off a message received from another node to a subsequent node. Each of the nodes comprises a transceiver receiving a message on the reference frequency from another node and transmitting the received message on the reference frequency to a subsequent node, and a controller controlling operation of the transceiver to receive the message transmitted by another node and to transmit the received message to a subsequent node.” ‘773 patent, 2:26-34.

	"Preferably, all Minion devices share a common structure in the form of a radio transceiver with antenna, microprocessor for controlling the transceiver, memory associated with the microprocessor and a power source." '773 patent, 6:48-52. "Additional objects includes providing a system a method which: *** shares network resources among low-cost intelligent data radios wherein the resources may include time synchronization, virtual geolocation services, sensor or actuator interfaces, shared memory and wide-area network access…." '773 patent, 1:59-2:23. "A number of major market areas have been identified most notably utility monitoring and control, intelligent transportation systems (ITS), mobile finance management, building automation and control, factory automation and control, home automation and control, security and access control, and asset management." '773 patent, 6:28-33. "The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as

In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of

	the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used

	for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery

	subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a “network message” field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet.” ‘252 patent, 55:40-59. ‘252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing “The Internet faces two serious scaling problems: address exhaustion and routing explosion.” Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 6,100,817 ("the '817 patent"), U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in

	the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses:

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of

	the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used

	for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery

	subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields.

	Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector comprising a redundancy check error detector;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.
wherein the controller sends preformatted command messages via the controller transceiver, and the plurality of transceivers send preformatted response messages; and	"FIG. 9A illustrates the overall operation of the microcontroller of a Minion device. The Minion device microcontroller is periodically energized from a power saving sleep mode to wake up mode at step 902 to listen for a message. If a message is received at step 904, the microcontroller is processed at step 906 as indicated in more detail below in FIG. 9C. … FIG. 9C illustrates the process of processing a message as

	indicted by step 906 of FIG. 9A. In particular, the microcontroller retrieves the message to be processed from the transmit queue at step 960, inserts its identification as the sender in step 962, records the transmit time and offset at step 964, and then proceeds to step 966 to determine whether or not the message contains a time field. If it does the microcontroller proceeds to step 968 to insert the current time in the field. Otherwise, the micro-controller proceeds to step 970 to compute the CRC for error detection (i.e., the cyclic redundancy check). It proceeds to step 974 to send the training bits followed by an encodes zero that is sent at step 976 followed by the bits which are sent in step 978." '217 patent, 10"27-33 and 13:6-19.
wherein at least one of the plurality of transceivers further sends preformatted emergency messages.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during

	special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
18. The system of claim 17, wherein the controller maintains periods of silence by not sending the preformatted command messages during predetermined time periods; and	The above contentions for claim 17 are hereby incorporated by reference. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. When such an extreme fault condition occurs, the monitor computer 418 "wakes up" from standby mode, processes the signal from its one or more

	sensors 408, and transmits a data packet consisting of the machine monitor's identification code and the sensor data to the command station 6. To avoid interference with regularly scheduled data messages, these fault messages are transmitted only during special tie intervals which are individually assigned to each machine monitor 4 specifically for the transmission of fault messages." '491 patent, 17:13-28. U.S. Patent No. 6,366,217, discloses that "[t]he information signal contains the data collected by the sensor interface module, or the emergency code." '217 patent, 13:66-14:1. U.S. Patent No. 5,874,903 discloses that CEBus protocol "preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting." '903 patent, 3:47-50.
wherein the at least one of the plurality of transceivers detects a period of silence and sends the preformatted emergency message during the period of silence.	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation. For example, U.S. Patent No. 5,907,491 discloses that "[w]hile it is preferable to transmit a signal from the machine monitor 4 to the command station 6 only at scheduled times, it is contemplated that the machine monitor 4 could also incorporate means of continuously sensing an extreme fault condition of the machine being monitored, such as the use of tuned reed switches for detecting an extreme vibration condition. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would

	have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252

	patent, 39:28-43. ‘252 patent, Figure 31. “For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module’s assigned tier address for that network service module to be addressed.” ‘252, 42:18-39. “FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and “network message” field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. …

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a sender address comprising an unique address of the sender;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." '773 patent, 14:5-20.
a command indicator comprising a command code;	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as

	determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ‘’773 patent, 14:5-20. "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." ‘773 patent; 22:13-19. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘773 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the ‘217 patent"), U.S. Patent No. 5,907,491 ("the ‘491 patent"), U.S. Patent No. 5,963,650 ("the ‘650 patent"), U.S. Patent No. 6,100,817 ("the ‘817 patent"), U.S. Patent No. 5,874,903 ("the ‘903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special

	requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	3:2. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '773 patent, it would

	have been obvious to a person ordinary skill in the art to combine and/or modify the '773 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: “FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers.” ‘252 patent, 38:34-43. ‘252 patent, Figure 25. “The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll.” ‘252

	patent, 39:28-43. ‘252 patent, Figure 31. “For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module’s assigned tier address for that network service module to be addressed.” ‘252, 42:18-39. “FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and “network message” field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. …

Exhibit P7 – Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 7,027,773

	Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for

	extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector that is a redundancy check error detector; and	"The messages handled by the MinionNet network can be thought of as being 32 bytes long and transferred at 9600 baud, although other data rates ate feasible. Each Minion device has a unique 32-bit serial number assigned during manufacture. … Each message will contain space for four of those serial numbers: (1) the message originator, (2) the message final destination, (3) the device actually transmitting for this hop, and (4) the intended receiver for this hop. Messages also contain a set of standard fields for message type codes, device status bits, message priority and handling bits. A payload area will contain application specific data such as geolocation information, time/date, etc., as determined by the message type codes. In addition, the protocol specifies a cyclic redundancy check (e.g., CRC) used to detect errors encountered during transmission." ''773 patent, 14:5-20.
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"The hop-to-hop routing is the same as for basic Minion device operation. Note that the burst data protocol causes an entire message to hop intact from one Minion device to the next." '773 patent, 15:30-33.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

The '492 Patent – Claim	U.S. Patent No. 6,100,817
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a receiver address comprising a scalable address of at least one remote device;	"Destination Address" at '817 patent, 6:45-55 (CEBUS Frame).

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin

	page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module,

	but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." a command indicator comprising command code;	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-

	3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the

	monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses:

	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a data value comprising a scalable message; and	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes.

	The number of bytes in the information filed available for application information is summarized for different types of packets." ‘’817 patent, 15:22-47. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding

	through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one

	individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field),

	message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June

a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is

	preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	'817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.

a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
at least one sensor associated with at least one of the transceivers to detect a condition and output a data signal to the transceiver; and	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
at least one actuator associated with at least one of the transceivers to activate a device.	"Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation

	of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the

	individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "For group response messages in the preferred embodiments, the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command." '817 patent, 4:17-21. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "After a meter receives the node message and is waiting to transmit the response, it will use a Link layer filter to prevent other packets (responses to the node from other meters, etc.) from being passed to the meter application. This prevents the meter application from continually reading and processing received messages while waiting to transmit a response." '817 patent, 12:17-23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers,

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the

	length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. wherein the message has a packet comprising a command indicator comprising a command code, a scalable data value comprising a scalable message, and an error detector that is a redundancy check error detector; and	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the

	utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "For group response messages in the preferred embodiments, the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command." '817 patent, 4:17-21. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length).

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	"A.Packet Headers Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets:

	U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the

	nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

	Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In the preferred embodiments of the invention, each response message from a meter contains the meter's unique address, and the Address Mask field is defined differently for meter response messages. For meter response messages, the bits of the Address Mask field are used by meters functioning as repeaters to indicate message transfer failure." '817 patent, 3:64-4:4. "No two meters responding to a message from the node are configured with the same timeslot but all meters responding to the message are configured with the same window size." '817 patent, 4:28-32.
9. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	The above contentions for claim 8 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18

	preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. "817 patent, Figure 1.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message

	… To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service

	module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner

	disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23.

	"A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the

	command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "1. The Basic CEBUS Protocol" '817 patent, 6:44-55 (CEBUS frame table showing Chksum).
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C,

	. . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a transceiver configured to send and receive wireless communications; and	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol;

	and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered

	'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.

	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR

	message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "For group response messages in the preferred embodiments, the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command." '817 patent, 4:17-21. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network

	implementation:" fields including Message Length). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging."

	Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it

	selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

	In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module

	sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing

	performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In the preferred embodiments of the invention, each response message from a meter contains the meter's unique address, and

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	the Address Mask field is defined differently for meter response messages. For meter response messages, the bits of the Address Mask field are used by meters functioning as repeaters to indicate message transfer failure." '817 patent, 3:64-4:4. "No two meters responding to a message from the node are configured with the same timeslot but all meters responding to the message are configured with the same window size." '817 patent, 4:28-32.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or

	business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with

	the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-

	35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol,

transceiver to send preformatted command messages.	wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. '817 patent, 2:50-64. "For group response messages in the preferred embodiments, the

	node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command." '817 patent, 4:17-21. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more

	of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean,

	structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition

	device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link

	packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43

	illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in

	accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "For group response messages in the preferred embodiments, the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command." '817 patent, 4:17-21. "The address fields used by the AMR system are buried in the CAL User Defined Message in the information field." '817 patent, 7:33-35. "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message

	… To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "After a meter receives the node message and is waiting to transmit the response, it will use a Link layer filter to prevent other packets (responses to the node from other meters, etc.) from being passed to the meter application. This prevents the meter application from continually reading and processing received messages while waiting to transmit a response." '817 patent, 12:17-23. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header

	and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43.

'817 patent, 12:23-34. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example,

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than

	they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition

	device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link

	packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for

Exhibit P8 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 6,100,817

	each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43

	illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

The '661 Patent – Claim	U.S. Patent No. 6,100,817
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

	prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. Figure 1.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.

	disconnect switch drive circuit, and a set of analog transducers." '817 patent, 5:58-64. '817 patent, figures 1 and 2.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	"Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figure 3.

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address. Moreover, the node is also preferably capable of reading data of a selected group of meters with a single command." '817 patent, 3:27-31. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. 	the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figure 3.
9. A system for controlling a remote device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

	module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a target remote device having an actuator to be controlled;	"In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this

	limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging

	functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses:

	"The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "Each meter preferably has a unique address and the node is preferably capable

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

	of reading data of individual meters using the individual meters' unique address. Moreover, the node is also preferably capable of reading data of a selected group of meters with a single command." '817 patent, 3:27-31. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. Figure 1.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

	electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figure 3.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

Exhibit P8– Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 6,100,817

	'817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figure 3.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown, the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a

	disconnect switch drive circuit, and a set of analog transducers." '817 patent, 5:58-64. '817 patent, Figure 2. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34. To the extent that Plaintiffs contend that this claim limitation is not disclosed

	explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data

	acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN

Figure 1.
14. The system as defined claim 12, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 12 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

	'817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figure 3.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

The '692 Patent – Claim	U.S. Patent No. 6,100,817
1. A system for remote data collection, assembly, and storage comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a

	prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support

	As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of

information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated

	at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). 11. The system as defined in claim 1, wherein the gateway includes one selected from the group consisting of:	The above contentions for claim 1 are hereby incorporated by reference.
a modem for establishing a dial-up connection with a remote computer; a network card for communicating across a local area network; a network card for communicating across the WAN, a DSL modem; and an ISDN card to permit backup access to the computer.	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8.
12. The system as defined in claim 1, wherein the	The above contentions for claim 1 are hereby incorporated by reference.

gateway translates the select information, the transmitter identification, and the transceiver identification information to TCP/IP for communication over the WAN.	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249.

	Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.

13. The system as defined in claim 1, wherein the WAN is the Internet.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host

	protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers.” ‘650 patent, 8:42-44. “For example, the Internet allows weather data from DAs 102 located

	anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
14. The system as defined in claim 1, wherein the WAN is a dedicated Intranet.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. 	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
24. A method for controlling a system comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
remotely collecting data from at least one sensor;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An

	AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the

	network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
processing the data into a radio-frequency (RF) signal;	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
transmitting the RF signal, via a relatively low-power transceiver, to a gateway;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a

	prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR

	protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF

The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
34. The system defined in claim 32, wherein each wireless transmitter is configured to transmit a relatively low-power radio-frequency (RF) signal.	The above contentions for claim 32 are hereby incorporated by reference. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF

	module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
36. The system defined in claim 32, wherein the gateway translates the encoded electrical signal, the transmitter identification, and the transceiver identification information into TCP/IP for communicating over the WAN.	The above contentions for claim 32 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.

	Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
37. The system defined in claim 32, wherein the WAN in the Internet.	The above contentions for claim 32 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, Figure 1.
at least one wireless low-power RF transceiver configured to receive the RF signal from the gateway; said wireless transceiver configured to translate the RF signal to an analog output signal, the wireless transceiver electrically coupled with an actuator; and	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF

	module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18,

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
an actuator configured to receive the analog output signal from the wireless transceiver, the actuator further configured to translate the analog output signal into a response.	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
43. The system defined in claim 42, the system input signal comprising:	The above contentions for claim 42 are hereby incorporated by reference.
a concatenation of information including data from a sensor, transceiver identification information from the originating transceiver, and transceiver identification information for each transceiver that receives and repeats the RF signal.	"1. The Basic CEBUS Protocol" '817 patent, 6:44-7:17 (CEBUS frame table). "Destination Address" at '817 patent, 6:45-55 (CEBUS Frame). "Source Address" at '817 patent, 6:45-55 (CEBUS Frame). "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66. "Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message.

	1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes. The number of bytes in the information filed available for application information is summarized for different types of packets." ''817 patent, 15:22-47.
46. The system defined in claim 42, wherein the gateway translates the RF signal and the RF control signal into TC/IP for communication over the WAN.	The above contentions for claim 42 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

	‘817 patent, Figure 1. “FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1.” ‘817 patent, 6:1-8. ‘817 patent, Figure 3. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the ‘817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the ‘817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: “The PRNET can also be accessed from other networks via an Internet gateway.” Jubin page 23. Burchfiel discloses: “When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the

	destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26. “Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers.” ‘650 patent, 8:42-44.

	"For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
47. The system defined in claim 42, wherein the WAN is the Internet.	The above contentions for claim 42 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102.

	The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
48. The system defined in claim 42, wherein the WAN is a dedicated Intranet.	The above contentions for claim 42 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and

	communications fields." '817 patent, 5:32-57. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1." '817 patent, 6:1-8. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." 51. The system as defined in claim 49, wherein the at least one gateway translates the RF signal and the RF control signal into TCP/IP for communication over the WAN.	The above contentions for claim 49 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or

	sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As

	shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
52. The system as defined in claim 49, wherein the WAN in the Internet.	The above contentions for claim 49 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example:

	Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
53. The system as defined in claim 49, wherein the WAN is a dedicated Intranet.	The above contentions for claim 49 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

	'817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.
54. The system as defined in claim 49, wherein the at least one gateway is connected to the WAN by a network selected from the group consisting of a telecommunications network, private radio-frequency network, and a computer network.	The above contentions for claim 49 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below.

	However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.
55. A method of collecting information and providing data services comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

adaptively configuring a data translator at the output of a local controller, wherein the data translator converts the output data stream into an information signal consisting of a transmitter code and an information field;	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
adaptively configuring at least one transmitter with the data translator, wherein the transmitter converts the information signal into a low-power RF signal;	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network

	(WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
placing a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically wherein the low power RF signal is received and repeated as required to communicate the information signal to a gateway, the gateway providing access to a WAN;	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.

	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
translating the low-power RF signal within the gateway to a WAN compatible data transfer protocol;	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.
transferring the translated low-power RF signal via the WAN to a computer wherein the computer is configured to manipulate and store data provided in said signal; and	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1

	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.
granting client access to the computer.	"FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.
56. The method of claim 55 wherein the WAN is the Internet.	The above contentions for claim 55 are hereby incorporated by reference. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
57. The method of claim 55 wherein the WAN is an Intranet.	The above contentions for claim 55 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or

	disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here….” ‘817 patent, 5:57-65. ‘817 patent, Figure 2. “Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled “System for Rate-Related Control of Electrical Loads.” This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter.” ‘817 patent, 2:11-30.
61. The method of claim 60, wherein the step of transmitting the RF control signal is further performed by at least one transceiver, wherein the transceiver is configured to receive and transmit the RF control signal.	The above contentions for claim 60 are hereby incorporated by reference. “FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail

	herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
62. The method of claim 60, wherein the network is the Internet.	The above contentions for claim 60 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "FIG. 3 schematically illustrates a communication protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing use of the TCP and IP protocols for communications among the server 20 (FIG. 1) and the node/collector units 18 (only one of which is shown in FIG. 1). In addition, the inventive protocol employs the CEBUS RF protocol, which is implemented by the node after receiving a request over the WAN. The CEBUS packet contains a packet in accordance with the ANSI meter protocol, and that packet in turn contains specific data for a given meter or meters." '817 patent, 6:1-13.

	To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks…." Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. "Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical

Exhibit P8 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 6,100,817

	to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way." Burchfiel page 250. The '650 patent discloses: "In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
63. The method of claim 60, wherein the network is an Intranet.	The above contentions for claim 60 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

The '732 Patent – Claim	U.S. Patent No. 6,100,817
1. A system for remote data collection, assembly, storage, event detection and reporting and control, comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art." '650 patent, 6:11-26. "Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present

	invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example: Jubin discloses: "The PRNET can also be accessed from other networks via an Internet gateway." Jubin page 23. Burchfiel discloses: "When some other network is present, it is important to provide connections between the terminals and hosts of the PRN and the terminals and hosts of the other network. This is being done for the ARPANET in two ways: 1. For communications with ARPANET hosts which support a protocol congruent with the PRN connection protocol (the Cerf-Kahn protocol mentioned previously qualifies here), the station functions as an

	extremely simple gateway: arriving packets are simply forwarded into the other network after their header format is converted to that of the destination network. … 2. The second approach will be conversion between the host-host protocols of the two networks….” Burchfiel page 249. Figure 4, Burchfiel page 249. Figure 5, Burchfiel page 250. “Finally, the PRN TELENT process performs the second type of gateway function described above: conversion between the PRN connection protocol and the ARPANET host-host protocol. Terminals on the PRN appear identical to the terminals attached to the PDP-11, and are able to access remote ARPANET service hosts in the same way.” Burchfiel page 250. The ‘650 patent discloses: “In the preferred embodiment, APPs 112 can access any appropriate DA 102. The purpose and timing of each access can vary from APP 112 to APP 112. However, some of the data used by each APP 112 may be the same. Therefore, by caching the data, the DA 102 does not have to regenerate it for each APP 112. This figure also illustrates that APPs 112 can reside within the processor 104 or at a remote location which accesses DAs 102 through the DCS. As shown, remote APPs 112 are connected to processor 104 by client connectors 110 (hereinafter CC 110) via RF links 114 or conventional telephone links 116. Those skilled in the art will recognize that the CCs 110 can be any suitable hardware and software needed to convert received data and commands to a form suitable for the software in the processor 104. The techniques required to implement a CC 110 are well known in the art.” ‘650 patent, 6:11-26.

	"Likewise, the APPS 112 may reside on a single DCS 100, or be distributed over a hierarchical network of computers." '650 patent, 8:42-44. "For example, the Internet allows weather data from DAs 102 located anywhere to be provided to a single APP 112." '650 patent, 10:54-57.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. Figure 1.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	"Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmit- ting transceivers, said gateway further configured to further transmit the	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain

translated information to the computer over the WAN and wherein at least one of said plurality of transceivers is also electrically interfaced with an actuator to control an actuated device.	embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. Figure 1. "In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as

	specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
13. In a system comprising a plurality of wireless devices configured for remote wireless communication and comprising a device for monitoring and controlling remote devices, the device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

a transceiver having a unique identification code and being electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and

	communications fields." '817 patent, 5:32-57. Figure 1. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. 	the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
16. The device of claim 13**,** wherein the data controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 13 are hereby incorporated by reference. "For group response messages in the preferred embodiments the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command. … Further still, in the presently preferred embodiments, the Group Response Select field allows the node to select one of a prescribed number of meter timeslots for the group response." '817 patent, 4:17-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command

	the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the

	system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
17. The device of claim 13**,** wherein the data controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code	The above contentions for claim 13 are hereby incorporated by reference. "For group response messages in the preferred embodiments the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command. … Further still, in the presently preferred embodiments, the Group Response Select field allows the node to select one of a prescribed number of meter timeslots for the group response." '817 patent, 4:17-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm

	message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
18. The device of claim 13, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the data controller can implement.	The above contentions for claim 13 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses:

	"Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
19. The device of claim 13, further comprising an actuator configured to receive command data from the controller and in response implement the command.	The above contentions for claim 13 are hereby incorporated by reference. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a

	person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51.

	U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
31. A wireless communication system including wireless communication devices capable of wireless communication, the wireless communication system comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817

	patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
at least one wireless communication device comprising a transceiver, the transceiver having a unique identification code and being interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from another wireless transceiver in a predetermined signal type;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control transceiver operations and receive data from the sensor, the controller configured to format data packets for transmission via the transceiver with at least some data packets comprising data representative of data sensed with the sensor; and	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
wherein the controller is configured to receive control signals from a data packet and based on the control signals send instructions to an actuator to implement a command.	"Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within

	the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
32. The wireless communication system of claim 31, further comprising at least one gateway connected to a WAN configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated	The above contentions for claim 31 are hereby incorporated by reference. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of

with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to a computing device over the WAN.	utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated

	at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "The Source Address field is preferably used for repeated addresses to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 4:45-47. "1.2 Destination and Source Address Fields In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond o messaged which are from their assigned node. Moreover, all packets will be broadcast, and will therefore contain NULL Destination House Code and Destination Address fields. … If the Source Address field is non-zero, repeaters are being used to transfer the [packet between the node and the end meter." '817 patent, 7:18-31. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly,

	with single repeats or with dual repeats." '817 patent, 12:23-34.
33. The wireless communication system of claim 31, further comprising a computing device configured to receive user input and based on user input, the computing device formatting control signals, and wherein the controller is configured to receive the control signals via wireless transmission and take action based on the control signals.	The above contentions for claim 31 are hereby incorporated by reference. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "In the presently preferred embodiment of the subject invention, the Source

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	House Code is used to specify the ID of the concentrator node. Meters will typically only respond to messages which are from their assigned node." '817 patent, 7:18-23. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "The Source Address field is preferably used for repeated addresses to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 4:45-47. "1.2 Destination and Source Address Fields In the presently preferred embodiment of the subject invention, the Source House Code is used to specify the ID of the concentrator node. Meters will typically only respond o messaged which are from their assigned node. Moreover, all packets will be broadcast, and will therefore contain NULL Destination House Code and Destination Address fields. … If the Source Address field is non-zero, repeaters are being used to transfer the [packet between the node and the end meter." '817 patent, 7:18-31.

	"2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S> patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator."

	Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9

	during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements."

	'903, 4:23-31.
34. The wireless communication system of claim 31, wherein the controller is configured to provide one or more function codes in the data packet in response to data sensed by the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "For group response messages in the preferred embodiments the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command. … Further still, in the presently preferred embodiments, the Group Response Select field allows the node to select one of a prescribed number of meter timeslots for the group response." '817 patent, 4:17-36. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor

	4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions,

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,013,732 based on U.S. Patent No. 6,100,817

	commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
35. The wireless communication system of claim 31, wherein the controller comprises a memory containing a plurality of function codes specific to the sensor.	The above contentions for claim 31 are hereby incorporated by reference. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "For group response messages in the preferred embodiments the node is capable of eliciting individual responses from a selected group of meters by broadcasting a single command. … Further still, in the presently preferred embodiments, the Group Response Select field allows the node to select one of a prescribed number of meter timeslots for the group response." '817 patent, 4:17-36. "The command/response format typically used for meter communications is buried in the CAL User Defined Message field, and will adhere to the ANSI C12.18 standard protocol for meter communications." '817 patent, 9:37-40.

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

The '780 Patent – Claim	U.S. Patent No. 6,100,817
1. In a system comprising a plurality of wireless devices, a device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a transceiver having a unique identification code and being	"In the preferred embodiments of the invention, the CEBUS

electrically interfaced with a sensor, the transceiver being configured to receive select information and identification information transmitted from a second wireless transceiver in a predetermined signal type;	message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18

	preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
the transceiver being further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the second wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a controller operatively coupled to the transceiver and the sensor, the controller configured to control the transceiver and receive data from the sensor, the controller configured to format a data packet for transmission via the transceiver, the data packet comprising data representative of data sensed with the sensor.	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	'817 patent, Figure 1. "FIG. 2 is a more detailed block diagram of a utility meter synch as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
2. The device of claim 1, wherein the controller is configured to receive data packets comprising control signals and in response to the control signals provide a control signal to an actuator for implementation of a command.	The above contentions for claim 1 are hereby incorporated by reference. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.

	"Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine

	and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it

	selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

4. The device of claim 1, wherein the controller is configured to receive data packets comprising a function code, and in response to the function code, implement a function.	The above contentions for claim 1 are hereby incorporated by reference. "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps"

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
5. The device of claim 1, wherein the controller is configured to format data packets for transmission via the transceiver, the data packets comprising a function code corresponding to sensed data and the unique identification code that identifies the transceiver.	The above contentions for claim 1 are hereby incorporated by reference. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater

	functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface,

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
6. The device of claim 1, further comprising a memory to store one or more function codes corresponding to the device, the function codes corresponding to a number of functions the controller can implement.	The above contentions for claim 1 are hereby incorporated by reference. "FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the

	utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET,

	discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	page 248. U.S. Patent No. 5,907,491 discloses: “Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling.” ‘491 patent, 7:56-60. “During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity.” U.S. Patent No. 5,963,650 discloses: “Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices.” ‘650 patent, 5:46-51.

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	U.S. Patent No. 7,027,773 discloses: “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: “Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements.” ‘903, 4:23-31.
7. The device of claim 1, further comprising an actuator configured to receive command data from the controller and in response implement a command.	The above contentions for claim 1 are hereby incorporated by reference. “Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled “System for Rate-Related Control of Electrical Loads.” This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host

	site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special

	requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device

Exhibit P8– Invalidity Chart for U.S. Patent No. 8,754,780 based on U.S. Patent No. 6,100,817

	and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
8. The device of claim 1, wherein the second transceiver is nearby to the transceiver.	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.

	"Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35.

Exhibit P8 – Invalidity Chart for U.S. Patent No. 8,908,842 based on U.S. Patent No. 6,100,817

The '842 Patent – Claim	U.S. Patent No. 6,100,817
1. A device for communicating information, the device comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.
a low-power transceiver configured to wirelessly transmit a signal comprising instruction data for delivery to a network of addressable devices;	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1.
an interface circuit for communicating with a central location; and	"FIG. 1 depicts an AMR system comprising, in accordance with

	the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, figure 1.
a controller coupled to the interface circuit and to the low-power transceiver, the controller configured to establish a communication link between at least one device in the network of addressable devices and the central location using an address included in the signal, the communication link comprising one or more devices in the network of addressable, the controller further configured to receive one or more signals via the low-power transceiver and communicate information contained within the signals to the central location.	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. the controller further configured to receive one or more data signals from the central location via the interface circuit and communicate information contained within the signals to the remote device.	"FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface,

	digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, figure 1.

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

The '893 Patent – Claim	U.S. Patent No. 6,100,817
1. A system for communicating commands and sensed data between remote devices, the system comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters

transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a

	digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No.

	08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages;	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"1. The Basic CEBUS Protocol" '817 patent, 6:44-7:17 (CEBUS frame table).
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"Destination Address" at '817 patent, 6:45-55 (CEBUS Frame). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than

	they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are

	desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type

	ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending transceiver;	"Source Address" at '817 patent, 6:45-55 (CEBUS Frame).
a command indicator comprising a command code;	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "Further background information may be found in U.S. Pat. No.

	5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example,

	Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247.

	"A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses:

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	"Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "1.3 Information Field

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes. The number of bytes in the information filed available for application information is summarized for different types of packets." ''817 patent, 15:22-47. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual

	address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. 3. The system of claim 2, wherein the at least one integrated transceiver receives the preformatted command message requesting sensed data, confirms the receiver address as its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet, wherein the packets are equal to the number of segments.	The above contentions for claim 2 are hereby incorporated by reference. “In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol.” ‘817 patent, 2:50-64. “Information Field” at ‘817 patent, 6:45-55 (CEBUS Frame).

	"1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes. The number of bytes in the information filed available for application information is summarized for different types of packets." '’817 patent, 15:22-47. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link

	packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for

	each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43

	a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.
17. A system for communicating commands and sensed data between remote devices, the system comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface,

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
a plurality of transceivers, each transceiver being in communication with at least one other of the plurality of transceivers, wherein each transceiver has a unique address, wherein the unique address identities an individual transceiver, wherein each transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with the other transceivers via preformatted messages;	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF

	communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57. '817 patent, Figure 1. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34.
a controller, connected to one of the plurality of transceivers, the controller being in communications with each of the plurality of transceivers via a controller transceiver, the controller communicating via preformatted messages, wherein the preformatted messages comprises at least one packet, wherein the packet comprises:	"FIG. 2 is a more detailed block diagram of a utility meter such as meter 12A. A s shown the exemplary meter 12A includes a display, a metering board (e.g., including analog to digital convertors, a digital signal processor, etc., for performing the metering function), a power supply, a CEBUS RF board, a disconnect switch drive circuit, and a set of analog transducers. Again, such utility meters are well known and therefore will not be described in detail here…." '817 patent, 5:57-65. '817 patent, Figure 2.
a receiver address comprising a scalable address of the at least one of the intended receiving transceivers;	"Destination Address" at '817 patent, 6:45-55 (CEBUS Frame). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers*

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse

	poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
sender address comprising the unique address of the sending	"Source Address" at '817 patent, 6:45-55 (CEBUS Frame).

transceiver;	
a command indicator comprising a command code;	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30. "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. To the extent that Plaintiffs contend that this claim limitation is

	not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses:

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	"The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data

	for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data,

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
at least one data value comprising a scalable message; and	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes. The number of bytes in the information filed available for application information is summarized for different types of packets." ''817 patent, 15:22-47. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine

	and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable

	fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43.

	'252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is

	identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields.

37. A method of communicating between geographically remote devices, the method comprising:	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "FIG. 1 depicts an AMR system comprising, in accordance with the present invention, a plurality of utility meters 12A, 12B, 12C, . . . 12D (for metering electricity, gas or water). Each of the meters has a corresponding CEBUS RF module for receiving RF

	communications from a node, or collector, 18, or sending RF communications to the node, and also for communication with a CEBUS local area network (LAN) within the residence or business with which the meter is associated. The node 18 preferably includes a wide area network (WAN) interface, a digital controller, and a CEBUS RF module. The WAN interface, digital controller, and CEBUS RF module are not described in detail herein since such devices are well known in the networking and communications fields." '817 patent, 5:32-57.
sending a message;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. "2.2 Group Responses CEBUS broadcast messages do not generate responses from the receiving devices. To utilize the communication bandwidth most efficiently, a fixed network needs to issue a single command to a

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	group of meters and get individual responses from each meter. Application layer timing at the node and meters will provide a mechanism for command/multiple response messaging." '817 patent, 11:27-35.
receiving the message at one or more of the remote devices;	"2.2 Group Responses CEBUS broadcast messages do not generate responses from the receiving devices. To utilize the communication bandwidth most efficiently, a fixed network needs to issue a single command to a group of meters and get individual responses from each meter. Application layer timing at the node and meters will provide a mechanism for command/multiple response messaging." '817 patent, 11:27-35.
processing the message;	"After broadcasting a message, the node will set a timer and wait for meter responses before it is allowed to broadcast another message. …Each meter is assigned a unique window during which its is allowed to broadcast a response to the node." '817 patent, 11:36-43. "After a meter receives the node message and is waiting to transmit the response it will use a Link payer filter to prevent other packets (responses to the node from other meters, etc.) from being passed to the meter application. This prevents the meter application from continually reading and processing received messages while waiting to transmit a response." '817 patent, 12:17-23.
preparing a response message;	"After broadcasting a message, the node will set a timer and wait for meter responses before it is allowed to broadcast another message. …Each meter is assigned a unique window during which its is allowed to broadcast a response to the node." '817 patent, 11:36-43.
receiving the response message;	"2.2 Group Responses

	CEBUS broadcast messages do not generate responses from the receiving devices. To utilize the communication bandwidth most efficiently, a fixed network needs to issue a single command to a group of meters and get individual responses from each meter. Application layer timing at the node and meters will provide a mechanism for command/multiple response messaging." '817 patent, 11:27-35.
processing the response message	"FIG. 3 schematically illustrates a communications protocol in accordance with the present invention. This protocol is explained in greater detail below. However, it may be briefly summarized as entailing the use of the TCP and IP protocols for communicating among the server 20 (FIG. 1) and the node/collector units 18 (only one is shown in FIG. 1)." '817 patent, 6:1-8. '817 patent, Figures 1 and 3.
wherein all messages comprise at least one packet, the packet having a predetermined format;	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS protocol." '817 patent, 2:50-64.
wherein the predetermined format comprises:	"1. The Basic CEBUS Protocol" '817 patent, 6:44-7:17 (CEBUS frame table).

a receiver address comprising a scalable address of the at least one of the intended receiving remote devices;	"Destination Address" at '817 patent, 6:45-55 (CEBUS Frame). To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed

	throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to

	eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and

	"network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
a sender address comprising an unique address of the sender;	"Source Address" at '817 patent, 6:45-55 (CEBUS Frame).
a command indicator comprising a command code;	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "Further background information may be found in U.S. Pat. No. 5,696,695, Dec. 9, 1997, titled "System for Rate-Related Control of Electrical Loads." This patent discloses a system that attempts to cover residential application of a variety of demand side management features. These features may be initiated at a host site and transmitted to a residence or could be accomplished locally. Communications are transmitted to devices in the home using CEBUS power line or RF technology. The system employs the generic CEBUS protocol as specified in the EIA documentation. The disclosed system, therefore, is an example of a system that could be installed at a residence prior to installation of an AMR network that utilizes CEBUS RF in the manner disclosed herein. Thus a system could be installed at a residence to handle several loads within the home, shifting power usage to match the pricing structure programmed into the electric meter." '817 patent, 2:11-30.

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	"In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. "Each meter preferably has a unique address and the node is preferably capable of reading data of individual meters using the individual meters' unique address." '817 patent, 3:27-29. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, U.S. Patent No. 5,874,903 ("the '903 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses:

	"PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60.

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	"During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet

	network." '773 patent; 22:13-19. U.S. Patent No. 5,874,903 discloses: "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
a scalable data value comprising a scalable message; and	"Information Field" at '817 patent, 6:45-55 (CEBUS Frame). "1.3 Information Field The Information field includes a NPDU header (Network layer header), an APDU header (Application layer header) and a CAL message. 1.3.1 NPDU Header The NPDU headers required for the fixed network system are 1-3 bytes in length. If a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header. … 1.3.3 CAL Message … To minimize the number of communication interfaces to the meter, the application layer of the C12.18 protocol is passed in a CEBUS CAL message using the Utility Meter Context and the CAL User Defined Message Structure." '817 patent, 7:55-10:11 (with CAL User Defined message format and fixed network

	implementation:" fields including Message Length). "4. Data thru-put The Information field in a CEBUS packet is limited to 32 bytes. The number of bytes in the information filed available for application information is summarized for different types of packets." ''817 patent, 15:22-47. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '817 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '817 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR,

	encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39.

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	"FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

	Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
an error detector that is a redundancy check error detector; and	"1. The Basic CEBUS Protocol" '817 patent, 6:44-55 (CEBUS frame table showing Chksum).
wherein the steps of sending and receiving are repeated until the message is received by the intended receiver.	"In sum, the present invention provides a method and system by which the CEBUS protocol can be utilized in an AMR fixed network RF system while maintaining commonality and compliance with other CEBUS equipment. An AMR system in accordance with the present invention comprises a plurality of utility meters, each meter comprising a radio frequency (RF) module for transmitting and receiving RF CEBUS message packets in accordance with a prescribed CEBUS protocol, wherein the CEBUS message packets contain embedded AMR message packets in accordance with a prescribed AMR protocol; and a node for accessing data stored by any one or a group of the utility meters via RF communications using the CEBUS

	protocol." '817 patent, 2:50-64. "Copending U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System," and U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks" disclose related inventions concerning the use of fixed RF networks for AMR applications with utility meters having CEBUS capabilities. For example, the '640 application teaches a way to make the RF system adaptive to read hard to access meters within the network, by permitting any meter in the network to operate as a repeater. Thus, referring to FIG. 1, meter 12D may be considered 'inaccessible' with respect to the responsible node 18. The node 18, which is coupled to the AMR server 20 by a telephone link or some other wired or wireless link, sends information to the 'inaccessible' meter 12D by routing it through, say, meter 12C, which in this example function as a repeater." '817 patent, 6:15-35. "2.2.1 Repeater Support As discussed earlier, the Source Address field is preferably used for repeater addresses (for a detailed understanding of the repeater algorithms, refer to U.S. patent application Ser. No. 08/870,640, filed Jun. 6, 1997, entitled "RF Repeater for Automatic Meter Reading System"; see also U.S. patent application Ser. No. 08/908,728, filed Aug. 7, 1997, entitled "Energy Meter with Multiple Protocols for Communication with Local and Wide Area Networks") to either implement RF communications that read meters directly, with single repeats or with dual repeats." '817 patent, 12:23-34

Exhibit P8– Invalidity Chart for U.S. Patent No. 6,914,893 based on U.S. Patent No. 6,100,817

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

The '492 Patent – Claim	U.S. Patent No. 5,874,903
1. In a communication system to communicate command and sensed data between remote devices, the system comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43.

	"The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a receiver address comprising a scalable address of at least one remote device;	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson:

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	"FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in

	several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by

	monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be

	used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.
a data value comprising a scalable message; and	"Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59.

	given application." 4:1-7.
2. The system of claim 1, further comprising:	The above contentions for claim 1 are hereby incorporated by reference.
a plurality of transceivers each having a unique address, the transceiver being one of the plurality of transceivers;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. '903 patent, Figure 1. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16.

	'903 patent, Figure 2. "This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C, … 12D, where meter 12D is considered 'inaccessible' (i.e., difficult to reach by direct RF communications) with respect to a responsible node 18." '903 patent, 5:4-8. '903 Figure 5. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
a plurality of controllers associated with each the controller associated with at least one of the transceivers, the controller being in communication with at least one other transceiver with a preformatted message, the preformatted message having at least one scalable field;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "In all cases, the two-way RF system can be utilized for read/write data required for the system (with all messages ported through the meter)." '903 patent 2:36-38. "The basic requirement for all the various systems mentioned

	above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14. The meter also includes a modem for so called dialback telephone communications with the AMR network, a UART transceiver, or the like, for communicating with the CEBus LAN 10, and a meter processor for controlling the metering functions as required for a given application." 4:1-7. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.

at least one sensor associated with at least one of the transceivers to detect a condition and output a data signal to the transceiver; and	"System Overview (FIGS 1-4) To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, an electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:16-24.
at least one actuator associated with at least one of the transceivers to activate a device.	"The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. '930 patent, Figure 2.
3. The system of claim 1, wherein the controller sends the preformatted message via an associated transceiver, and at least one transceiver sends the preformatted response message.	The above contentions for claim 1 are hereby incorporated by reference. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6.
4. The system of claim 1, wherein at least one transceiver receives the preformatted message requesting sensed data, confirms the receiver address as its own unique address, receives a sensed data signal, formats the sensed data signal into scalable byte segments, determines the number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 1 are hereby incorporated by reference. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs'

	stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the

	first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385,

To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example,

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than

	they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some

	anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition

	devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are

	desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type

	ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
providing a controller to determine if at least one received message is a duplicate message and determining a location from which the duplicate message originated.	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node

	or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
9. The method of claim 8, further comprising providing at least	The above contentions for claim 8 are hereby incorporated by

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

one remote wireless communication device, wherein at least one of the devices comprise geographically remote transceivers adapted to transmit and receive at least one message using radio frequency transmissions.	reference. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
10. The method of claim 8, further comprising providing at least one remote wireless communication device, wherein at least one of the devices has a unique address and the packet further comprises at least one scalable address field to contain the unique address for at least one device.	The above contentions for claim 8 are hereby incorporated by reference. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins

	with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Jubin, and other references as cited below. For example, Jubin, which is also directed to the PRNET, teaches: *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and

	fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g.,

	information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some

	information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
11. The method of claim 8, further comprising providing an actuator associated with at least one of the remote devices, the actuator configured to actuate in response to the command code.	The above contention for claim 8 is hereby incorporated by reference. "The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition

	to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. '903 patent, Figure 2. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected

	devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data

	transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information

	originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.
13. The method of claim 8, further comprising determining if an error exists in a packet of the at least one message.	The above contention for claim 8 is hereby incorporated by reference. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
14. A wireless communication device for use in a communication system to communicate command and sensed data between remote wireless communication devices, the wireless communication device comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to

	the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application),

	message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a transceiver configured to send and receive wireless communications; and	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. '903 patent, Figure 1. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2.

	"The AMR network 14, in the embodiment of FIG. 2. includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. '903 patent, Figure 2. "This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C, … 12D, where meter 12D is considered 'inaccessible' (i.e., difficult to reach by direct RF communications) with respect to a responsible node 18." '903 patent, 5:4-8. '903 Figure 5. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	"Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to format a message comprising a receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code, a data value comprising a scalable message.	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	"Referring now to FIG. 3, a pass through protocol useful in this system includes a CEBus protocol which in turn is embedded in a meter protocol." '903 patent, 4:20-22. '903 patent, Figure 3. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses:

	"From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). …

	Routing Header: The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by

	monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be

	used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first,

	broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a

	network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
15. The wireless communication device of claim 14, further comprising at least one sensor configured to detect a condition and output a signal to the controller.	The above contentions for claim 14 are hereby incorporated by reference. "System Overview (FIGS 1-4) To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, an electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:16-24.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

16. The wireless communication device of claim 14, wherein the controller is further configured to determine if at least one received message is a duplicate message and determine a location from which the duplicate message originated.	The above contentions for claim 14 are hereby incorporated by reference. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
17. The wireless communication device of claim 14, further comprising at least one actuator configured to implement an action corresponding to the command code.	The above contention for claim 14 is hereby incorporated by reference. "The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent,

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	3:53-67. '930 patent, Figure 2.
18. The device of claim 14, wherein the transceiver comprises a unique transceiver address to distinguish the transceiver from other transceivers.	The above contentions for claim 14 are hereby incorporated by reference. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
19. In a system for communicating commands and sensed data between remote devices comprising a communications device for communicating commands and sensed data, the communications device comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903

	patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a transceiver operably configured to be in communication with at least one other of a plurality of transceivers, wherein the	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver,

transceiver has a unique address, wherein the unique address identities the individual transceiver, wherein the transceiver is geographically remote from the other of the plurality of transceivers, wherein each transceiver communicates with each of the other transceivers via preformatted messages;	metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. '903 patent, Figure 1. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. '903 patent, Figure 2. "This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C, … 12D, where meter 12D is considered 'inaccessible' (i.e., difficult to reach by direct RF

	communications) with respect to a responsible node 18." '903 patent, 5:4-8. '903 Figure 5. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
a controller configured to be in communication with the transceiver, the controller configured to provide preformatted messages for communication;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "In all cases, the two-way RF system can be utilized for read/write data required for the system (with all messages ported through the meter)." '903 patent 2:36-38. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application),

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14. The meter also includes a modem for so called dialback telephone communications with the AMR network, a UART transceiver, or the like, for communicating with the CEBus LAN 10, and a meter processor for controlling the metering functions as required for a given application." 4:1-7. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31.
wherein the preformatted message comprises at least one packet, wherein the packet comprises: a receiver address comprising a scalable address of the at least one of the intended receiving transceivers; sender address comprising the unique address of the sending transceiver; a command indicator comprising a command	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node

code; at least one data value comprising a scalable message; and an error detector comprising a redundancy check error detector; and wherein the controller is configured to interact with the transceiver to send preformatted command messages.	or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "Referring now to FIG. 3, a pass through protocol useful in this system includes a CEBus protocol which in turn is embedded in a meter protocol." '903 patent, 4:20-22. '903 patent, Figure 3. "Meter information in a node protocol packet includes meter ID, a repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below.

	For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs'

	stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data

	transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information

	originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25.

	"The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the

	first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385,

	November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
20. The communication device of claim 19, further comprising a sensor operatively configured to detect a condition and output a sensed data signal that corresponds to the condition to the transceiver.	The above contentions for claim 19 are hereby incorporated by reference. "System Overview (FIGS 1-4) To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, an electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:16-24.
21. The communication device of claim 20, wherein the transceiver is configured to receive a preformatted command message requesting sensed data, confirms the receiver address is its own unique address, receives the sensed data signal, formats the sensed data signal into scalable byte segments, determines a number of segments required to contain the sensed data signal, and generates and transmits the preformatted response message comprising at least one packet.	The above contentions for claim 20 are hereby incorporated by reference. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more

	of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers* Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header

	corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command

	or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or

	destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information

	is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse poll network message format in the context of a data link packet." '252 patent, 55:40-59.

	'252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.
25. A wireless communication device for use in a communication system to communicate a number of commands and sensed data	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

between remote wireless communication devices, the wireless communication device comprising:	The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a transceiver configured to send and receive wireless communications; and	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. '903 patent, Figure 1. "The meter includes an RF transceiver for communicating normal

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. '903 patent, Figure 2. "This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C, … 12D, where meter 12D is considered 'inaccessible' (i.e., difficult to reach by direct RF communications) with respect to a responsible node 18." '903 patent, 5:4-8. '903 Figure 5. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to

	access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
a controller configured to communicate with at least one other remote wireless device via the transceiver with a preformatted message, the controller further configured to reformat a message comprising receiver address comprising a scalable address of at least one remote wireless device; a command indicator comprising a command code; a data value comprising a scalable	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format

message.	that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "In all cases, the two-way RF system can be utilized for read/write data required for the system (with all messages ported through the meter)." '903 patent 2:36-38. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14. The meter also includes a modem for so called dialback telephone communications with the AMR network, a UART transceiver, or the like, for communicating with the CEBus LAN 10, and a meter processor for controlling the metering functions as required for a given application." 4:1-7. "Meter information in a node protocol packet includes meter ID, a

	repeat count, data and destination address, and error detection bits. The data/destination bits of the meter protocol are passed through to the CEBus network and include source and destination addresses, data, and error detection bits. In presently preferred embodiments of the invention, the pass through protocols for the system are table based. The tables are designed to allow data, functions, commands, schedules, etc., to be passed to the different system elements." '903, 4:23-31. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FIG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FIG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. '903 patent, Figure 6. To the extent that Plaintiffs contend that this claim limitation is

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,697,492 based on U.S. Patent No. 5,874,903

	not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. *"A.Packet Headers*

	Every packet transmitted by every PR contains several headers, which add about 10 percent to the packet length. Each header corresponds to a protocol layer. Strict layering produces a clean, structured design, but also causes the headers to be longer than they could be because of duplication of some fields and fragmentation of other among the headers. The packet headers that are of concern to this paper are the end-to-end (ETE) header and the routing header. *ETE Header*: The ETE header is created by the source device. It contains the source device ID, which is use to update the PRs' stored device-PR correspondence data (Section III-C), and the destination device ID, which is used in forwarding (Section IV-B). … *Routing Header:* The routing header is created by the source PR, encapsulating the ETE header." Jubin page 25 (see Table for routing header fields). "The routing header stays on the packet throughout its forwarding through the PRNET subnet. The source PR ID, sequence number, and destination PR ID created by the source PR stay fixed throughout the packet's journey to the destination PR. The rest of the fields are updated by every intermediate packet radio." Jubin page 25-26. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports

	debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity." U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the

	preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2. In addition, the following references disclose the use of scalable fields in radio packets: U.S. Patent No. 5,673,252 to Johnson: "FIG. 25 depicts the structure of a well-known standard data link packet, the HDLC frame format. Using this structure, flag fields

	demark the start and end of the packet, and implicitly define the length of the variable length information field. The source or destination address is specified in an expanding, in byte units, address field. An 8-bit, or 16-bit, if larger sequence numbers are desired, control field identifies the type of the packet, e.g., information, supervisory or unnumbered, and contains send and receive sequence numbers." '252 patent, 38:34-43. '252 patent, Figure 25. "The wide area communications network data ink layer uses three delivery mechanisms for messages on the RND link. The first, broadcast to class address, is used for messages which are supposed to be received by all network service modules belonging to a particular class, usually based on network service module type. FIG. 31 illustrates an RND broadcast to class address data link packet structure. The second, broadcast to individual address, is used for messages intended for one individual network service module; the message is periodically transmitted and the network service module is expected to eventually hear the message. The third, reverse poll, is also used for messages intended for one individual network service module, but a message is not transmitted until the network service module sends a message explicitly requesting the reverse poll." '252 patent, 39:28-43. '252 patent, Figure 31. "For network service modules, broadcast addressing arises in several different circumstances, and is handled differently for each. Some information is intended for all network service

	modules, and is identified only by the slot/subchannel the information occupies; no address is specified. Some information is intended for only one network service module, and network service module type and address are required; alternatively, type ay be omitted if implied by subchannel. Finally, some information is intended only for a subset, or tier, of the network service modules of a particular type. In this case, all network service modules will recognize a tiered address have, in addition to their normal ID, a 24-bit tier address assigned to them. A tiered address, on a transmitted packet, includes two parts, the first is a 24-bit pattern and the second is a 24-bit mask selecting which of the pattern bits must match corresponding bits of a network service module's assigned tier address for that network service module to be addressed." '252, 42:18-39. "FIG. 42 illustrates an RND broadcast to class network message format in the context of a data link packet. A complete message includes: optional address (nsmtyp-Data Link packet field), message (cofftend) type, application specific control subfield and an application message. The address may only be omitted, and "network message" field enlarged by 8 bits, if the delivery subchannel is dedicated to a single network service module type. Each application is responsible for any message sequencing performed. … Delivery to individually addressed network service modules is identical in principle to the broadcast to class address except the nmsadr portion of the data link address field must be present, resulting in a "network message" field which is 32 bits smaller. This message structure is used both for broadcast to individual address and for reverse poll delivery mechanisms. FIG. 43 illustrates an RND broadcast to individual address and reverse

	poll network message format in the context of a data link packet." '252 patent, 55:40-59. '252 patent, Figures 42 and 43. In addition, a number of Network Working Group, Request for Comment publications discuss the use of scalable fields in IP addressing: Network Working Group Request for Comments No. 1385, November 1992, Z. Wang, disclosing "The Internet faces two serious scaling problems: address exhaustion and routing explosion." Wang discloses and Extended Internet Protocol that uses an EIP extension of variable length that holds the Source Network field and Destination Network field as an extension to addressing space. Network Working Group Request for Comments No. 986, June 1986, R. Callon & H. Braun, disclosing variable size address fields. Network Working Group Request for Comments No. 1365, September 1992, K. Siyan, disclosing "shortage of network numbers that can be assigned" for IP addressing and proposal for extending addressing fields. Network Working Group Request for Comments No. 1375, October 1992, P. Robinson, recognizing need for additional Internet address space as the Internet becomes more commercialized and proposing extensions for IP addressing.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

The '661 Patent – Claim	U.S. Patent No. 5,874,903
1. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message

	displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "Node 18 is called the "responsible" node in this example because it has primary responsibility for communicating with meters 12A-12D, although it is possible for more than one node to have the ability to communicate with a given node." '903 patent, 5:9-13. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communication link." '903 patent, 5:15-17. '903 patent Figures 2 and 5.
a plurality of transceivers dispersed geographically at defined locations, each transceiver electrically interfaced with a sensor and configured to receive select information and identification information transmitted from another nearby wireless transceiver	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "To make an AMR system adaptive to higher functions, a variety of

electrically interfaced with a sensor in a predetermined signal type and further configured to wirelessly retransmit in the predetermined signal type the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with the transceiver making retransmission; and	communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
at least one gateway connected to the wide area network configured to receive and translate the select information, the identification information associated with the nearby wireless transceiver, and transceiver identification information associated with one or more retransmitting transceivers, said gateway further configured to further transmit the translated information to the computer over the WAN.	'903 patent, Figure 2. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communications link." '903 patent, 5:15-17.
5. A system for monitoring remote devices, comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network.

	The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
at least one sensor adapted to generate an electrical signal in response to a physical condition;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	controller." '903 patent, 2:11-13. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2.
at least one wireless transmitter electrically interfaced with the sensor and configured to encode the electrical signal, the wireless transmitter further configured to transmit the encoded electrical signal and transmitter identification information in a radio-frequency (RF) signal;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16.

	"Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10.
one or more additional wireless transmitters each electrically interfaced with a sensor and configured to receive the RF signal and retransmit the RF signal;	"To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14. The meter 12 utilizes a two-way RF protocol, for communicating with the AMR network 14, that allows very cost effective meter reading to take place." '903 patent, 3:17-22. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21.
at least one gateway connected a wide area network (WAN) configured to receive and translate the retransmitted RF signal, the gateway further configured to deliver the encoded electrical signal and transmitter identification information to a computer on the WAN; and	'903 patent, Figure 2. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communications link." '903 patent, 5:15-17.
a computer configured to execute at least one computer program that formats and stores select information responsive to the electrical signal for retrieval upon demand from a remotely located device.	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "Node 18 is called the "responsible" node in this example because it has primary responsibility for communicating with meters 12A-12D, although it is possible for more than one node to have the ability to communicate with a given node." '903 patent, 5:9-13. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communication link." '903 patent, 5:15-17.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	'903 patent Figures 2 and 5.
6. The system of claim 5, wherein the at least one gateway is permanently connected to the WAN.	The above contentions for claim 5 are hereby incorporated by reference. '903 patent, Figure 2. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communications link." '903 patent, 5:15-17.
8. The system of claim 5, wherein the gateway translates the encoded electrical signal, the transmitter identification and the transceiver identification information into TCP/IP for communication over the WAN.	The above contentions for claim 5 are hereby incorporated by reference. '903 patent, Figure 3.
9. A system for controlling a remote device comprising:	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18.
a target remote device having an actuator to be controlled;	"The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43.

	"The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure, etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in

	memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity.” U.S. Patent No. 5,963,650 discloses: “Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices.” ‘650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: “The Data portion of a MinionNet network Standard Message with a Type Code meaning “Command” will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network.” ‘773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: “In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control.”

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

	'817 patent, 2:65-3:2.
a computer configured to execute at least one computer program that generates at least one control signal responsive to a system input signal; said computer integrated with a wide area network (WAN);	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "Node 18 is called the "responsible" node in this example because it has primary responsibility for communicating with meters 12A-12D, although it is possible for more than one node to have the ability to communicate with a given node." '903 patent, 5:9-13. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communication link." '903 patent, 5:15-17. '903 patent Figures 2 and 5.
a gateway connected to the WAN configured to receive and translate the at least one control signal	"The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communication link." '903 patent, 5:15-17.
a wireless transmitter coupled with the gateway for transmitting a wireless signal that contains the control signal;	'903 patent, Figure 2. "The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system

	for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67.
a first wireless transceiver electrically interfaced with an actuator for receiving the wireless signal and further retransmitting the wireless signal to the target remote device; and	"The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. '903 patent, Figure 2.
logic coupled to the target remote device for extracting the control signal from the retransmitted wireless signal and imparting an action on the actuator in response to the extracted control signal.	"FIG 4 is a more detailed block diagram of a solid state electronic meter 12. As shown, the meter 12 includes a control processor; communications processor; clock; memory; analog-to-digital (A/D) convertor (for digitizing input voltage and current measurements); math coprocessor energy, demand and time of use processors, and button, display, and relay handlers. The various processor functions may be implemented with one or more microprocessors or digital signal processors controlled by various firmware or software modules, and the button, display and relay handlers may be implemented with combinations of hard wired circuitry and/or software or firmware. One or more serial buses are employed for communications between

	the meter display and control buttons (where the relay, display, and buttons may be part of the CEBus LAN 10 (FIG. 2)." '903 patent, 4:42-57. '903 patent Figure 4. To the extent that Plaintiffs contend that this claim limitation is not disclosed explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, Kahn, Jubin, Burchfiel, U.S. Patent No. 6,366,217 ("the '217 patent"), U.S. Patent No. 5,907,491 ("the '491 patent"), U.S. Patent No. 5,963,650 ("the '650 patent"), U.S. Patent No. 7,027,773, ("the '773 patent"), U.S. Patent No. 6,100,817 ("the '817 patent") or other references as cited below. For example, Kahn, which is also directed to the PRNET, discloses: "From the station, parameters in each PR and terminal device in the network can be set remotely, selected elements can be halted, if appropriate, the collection of statistical data from selected devices may be enabled, traffic sources may be turned on or off, and data collection may be initiated." Kahn, page 1495. Similarly, Jubin, which is also directed to the PRNET, discloses: "PRs can also be loaded and debugged from a remote host computer. All the commands available to a local operator are available to a remote operator." Jubin page 23. "A plethora of terminal commands – display memory, alter memory, select/display trace breakpoint, display state, execute jobs, execute procedure,

	etc.—are available for local debugging." Jubin page 23. Also, Burchfiel, which is also directed to the PRNET, discloses: "The "function fields" provides an address: within a PRU, it selects the control process, the debugging process, or the measurement process." Burchfiel page 247. "A level-3 debugging protocol has been defined which supports debugging of remote PRU's from terminals attached to a central station. The debugging functions include examining and depositing words into the PRU memory, and setting "mousetraps" which send an error code to the controlling station when some anomalous condition occurs, e.g., hardware failure." Burchfiel page 248. U.S. Patent No. 5,907,491 discloses: "Special requests for data sensing, data analysis, data transmission, and data storage can also be transmitted by the command station 6 to one or more monitors 4. Such special requests are additional to the data and functions provided by monitors 4 during normal status polling." '491 patent, 7:56-60. "During normal communications, the monitor 4 powers up once every 60 seconds. As data is acquired by the monitors 4, it is preferably stored in memory 422 for a period of time. When the monitor transmits an alarm message to the command station 6, the command station 6 may then command the monitor to transmit its most recently stored data. For example, the monitor 4 can be programmed (either at the factory before being shipped, by the ICU 9 during installation or reconfiguration, or through appropriate wireless commands transmitted by the command station 6 before, during, or after installation) to store spectral data for each vibration measurement obtained during the most recent week of measurement activity."

	U.S. Patent No. 5,963,650 discloses: "Another advantage of the intelligent RF transceiver in the preferred embodiment is that it is capable of peer-to-peer operation. For example, a user application can issue a command or query to one data acquisition device and that data acquisition device can then communicate directly with other data acquisition devices." '650 patent, 5:46-51. U.S. Patent No. 7,027,773 discloses: "The Data portion of a MinionNet network Standard Message with a Type Code meaning "Command" will contain information originating with the MinionNet network Control Center that causes certain operations to be performed by the Minion device and results to be sent back to the Control Center. This can be used to set operating modes or data throughout the MinionNet network." '773 patent; 22:13-19. U.S. Patent No. 6,100,817 discloses: "In the preferred embodiments of the invention, the CEBUS message packets provide fields for addressing individual meters and groups of meters, for performing multi level repeater functions, authentication/password control." '817 patent, 2:65-3:2.
10. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the	"The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the

Exhibit P9 – Invalidity Chart for U.S. Patent No. 7,468,661 based on U.S. Patent No. 5,874,903

wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and

	which RPT from the RPT field." '903 patent, 7:2-3.
11. The system of claim 9, further comprising:	The above contentions for claim 9 are hereby incorporated by reference.
a plurality of additional wireless transceivers each coupled to an actuator or a sensor and configured to receive the wireless signal and to retransmit the wireless signal, wherein one of the plurality of additional wireless transceivers receive the wireless signal from the wireless transmitter and another one of the plurality of the additional wireless transceivers retransmits the wireless signal to the first wireless transceiver.	"The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. '903 patent, Figure 2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the

'903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
12. A system for remote data collection, assembly, storage, and event detection and reporting, comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract.

	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a computer configured to execute at least one	"The present invention provides a utility meter for use in an AMR network.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,874,903

The '692 Patent – Claim	U.S. Patent No. 5,874,903
1. A system for remote data collection, assembly, and storage comprising:	"An automatic meter reading system utilizes repeater technology to access hard to read meters within a fixed network structure. The components of the radio system that are needed for two-way communications are employed without adding significant cost to the meter. Using this approach, each meter in the network has the ability to repeat messages as required." '903 patent, abstract. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The present invention also provides a method for operating a utility meter used in connection with a fixed automatic meter reading (AMR) network. The inventive method comprises the steps of: receiving a message originated by an AMR node; determining whether the message is to be repeated; if the message is not to be repeated, determining whether the meter must respond to the message and, if so, transmitting a responsive message containing meter data; and if the message must be repeated, creating a modified message and transmitting the modified message. In accordance with the invention, the modified message is formatted to be receivable by another meter in the AMR network." '903 patent, 2:32-43. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message

	displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60.
a computer configured to execute at least one computer program that formats and stores select information for retrieval upon demand from a remotely located device, said computer integrated with a wide area network (WAN);	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "Node 18 is called the "responsible" node in this example because it has primary responsibility for communicating with meters 12A-12D, although it is possible for more than one node to have the ability to communicate with a given node." '903 patent, 5:9-13. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communication link." '903 patent, 5:15-17. '903 patent Figures 2 and 5.
at least one wireless transmitter configured to transmit select information and transmitter identification information;	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable

	to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be

Exhibit P9 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,874,903

	summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
a plurality of relatively low-power radio-frequency (RF) transceivers dispersed geographically at defined locations configured to receive select information transmitted from at least one nearby wireless transmitter and further configured to transmit the select information, the transmitter identification information and transceiver identification information; and	"The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic

	meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3.

	(For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3.
at least one gateway connected to the wide area network configured to receive and translate the select information, the transmitter identification information, and transceiver identification information, said gateway further configured to farther transmit the translated information to the computer over the WAN.	'903 patent, Figure 2. "The node 18 is coupled to an AMR server 20, e.g., by a telephone link or some other wired or wireless communications link." '903 patent, 5:15-17.
3. The system as defined in claim 1, wherein each wireless transmitter is configured to transmit a relatively low-power, radio-frequency (RF) signal.	The above contentions for claim 1 are hereby incorporated by reference. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23.

	"To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2. "The AMR network 14, in the embodiment of FIG. 2. Includes an RF node 14A (actually a plurality of such nodes) and a host computer, or server, 14B (or multiple hosts, as needed)." '903 patent, 4:14-16. "To make the RF system adaptive to read the hard to access meters within the network, it would be advantageous to have a method by which the node transceiver could be effectively moved closer to the heard to access meter. The present invention provides just such a method by allowing any meter in the network to be a repeater. This concept is depicted in FIG. 5, which schematically depicts a plurality of meters 12A, 12B, 12C…, 12D, where meter 12D is considered 'inaccessible" (i.e., difficult to reach by direct RF communication) with respect to a responsible node 18. … With the present invention, information from the AMR node 18 that does not each the 'inaccessible" meter 12D can be routed through a meter (e.g., meter 12C) that the node does reach and has the capability to reach the hard to access meter." '903 patent, 4:66-5:21.
4. The system as defined in claim 1, wherein each wireless transmitter is integrated with a sensor.	The above contentions for claim 1 are hereby incorporated by reference. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a

	controller." '903 patent, 2:11-13. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23. "To make an AMR system adaptive to higher functions, a variety of communication protocols may be incorporated into a solid state meter. As shown in FIG. 1, the AMR system includes a CEBus LAN 10, and electronic meter 12 (actually a plurality of such meters and LANs), and a fixed AMR network 14." '903 patent, 3:17-22. "The meter includes an RF transceiver for communicating normal and exception AMR traffic to the AMR network 14." '903 patent, 4:1-2.
5. The system as defined in claim 1, wherein the RF signal transmitted by the receiver contains a concatenation of information comprising select information and transmitter identification information from the originating transmitter and transceiver identification information for each transceiver that receives and repeats the RF signal.	The above contentions for claim 1 are hereby incorporated by reference. "The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67.

Exhibit P9 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,874,903

	'903 patent, Figure 2. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18. "Referring now to FIG. 6, the method of operation of a given meter will now be summarized. The inventive method begins with the reception of a message (step S1). Next, the meter determines whether this is a message to be repeated (step S2). This is accomplished by examining the "repeat" field of the meter protocol (FOG. 3). If the message is to be repeated, i.e., is intended for a downstream meter (such as meter 12D of FOG. 5), the meter modifies the message (step S3) and then retransmits it as an ASK signal that may be received by the other meters (step S4). The message is modified in step S3. (For example, the message may be modified by changing a two-bit field to indicate the end meter is to respond (e.g., the filed may be changed from "10" to "00")….If, on the other hand, the message is not to be repeated (as determined at step S2), meaning that this meter is the intended recipient, the meter determines whether it must respond (step S5) and if so, transmits an appropriate response (step S6) in the FSK format for reception by the node 18." '903 patent, 5:56-6:10. Figure 6. "The node knows which meter the data is from by the unique address and which RPT from the RPT field." '903 patent, 7:2-3. To the extent that Plaintiffs contend that this claim limitation is not disclosed

	explicitly or inherently in the '903 patent, it would have been obvious to a person ordinary skill in the art to combine and/or modify the '903 patent with the teachings of one or more of the additional references teaching this limitation, for example, U.S. Patent No. 6,100,817, which discloses "[i]f a message does not fit into the 32 byte Information field, the message is segmented into multiple packets. A segmented message requires a 3 byte NPDU header. Messages fitting into the 32 byte Information field only require a 1 byte NPDU header." '817 patent, 7:61-66.
6. The system as defined in claim 5, wherein the at least one transmitter is replaced by a transceiver, the transceiver further integrated with an actuator.	The above contentions for claim 5 are hereby incorporated by reference. "The CEBus protocol provides a link to a remote residential display for simple AMR as well as higher functions. In addition to the display capability, CEBus provides a peer-to-peer communication capability which allows the meter to pass through information to any other device that is on the CEBus LAN 10. This effectively allows the meter to be the gateway into the residential system for all levels of communications requirements. FIG. 2 provides a more detailed illustration of the system. As shown, the CEBus LAN 10 includes a thermostat/display device 10A that can be used by the meter to display information to the customer (via CEBus communications). In addition, the LAN 10 may include relay 10B, lighting 10C and security 10D subsystems that may be controlled through the CEBus protocol." '930 patent, 3:53-67. '903 patent, Figure 2.
7. The system as defined in claim 6, wherein the transceivers are configured to communicate with the gateway via a RF signal.	The above contentions for claim 6 are hereby incorporated by reference. "The present invention provides a utility meter for use in an AMR network. The meter includes a radio frequency (RF) transceiver, metering means, and a controller. The meter is programmed to receive a message from an AMR node

Exhibit P9 – Invalidity Chart for U.S. Patent No. 6,437,692 based on U.S. Patent No. 5,874,903

	via the RF transceiver and, depending on the content of the message, to respond to the node or repeat the message by sending a modified message in a format that is receivable by another meter in the AMR network." '903 patent, 2:11-18.
8. The system as defined in claim 7, wherein the computer is further configured to respond to received select information by communicating a control signal to at least one transceiver, wherein the actuator integrated with the transceiver is responsive to the control signal.	The above contentions for claim 7 are hereby incorporated by reference. "The basic requirement for all the various systems mentioned above is a robust two-way RF protocol that links the meter with a host computer of the AMR network 14. This protocol must have the capability to pass messages through the meter 12 into the CEBus network 10. This pass through signaling permits rate management for electricity (in an electric meter application), message displays for customer alerts, demand side management deployment and other activities. The protocol preferably also has the capacity to allow the meter to report by exception for events such as security related activities and outage reporting. This capability within the RF protocol for advanced functions is included without burdening the basic capability of the meter to accomplish simple AMR in a very cost effective manner." '903 patent, 3:39-60. "In one presently preferred embodiment of the invention, the meter is operable to receive messages transmitted with a first prescribed signal type, to transmit responsive messages with a second prescribed signal type, and to repeat messages with the first prescribed signal type." '903 patent, 2:19-23.
