

- 30 -

2. An event recording apparatus for use in an automotive vehicle environment, comprising:
- 5 (a) a removable data storage card including non-volatile memory means for storing data, and a first interface means for transmitting data from the memory means and for receiving data for storage in the memory means;
 - 10 (b) an interface adapter, adapted to removably receive the data storage card and mountable in an automotive vehicle, and including a second interface means for transmitting data to the first interface means of the data storage card and for receiving data from the first interface means of the data storage card;
 - 15 (c) at least one data generating means, adapted to be mounted in an automotive vehicle, each for sensing an environmental or an operational parameter of the automotive vehicle and for generating corresponding data values;
 - 20 (d) controller means, coupled to the interface adapter and to at least one data generating means, for receiving data values from at least one data generating means and transmitting such received data values through the interface adapter for storage in the data storage card, the controller means including means for reading data from the data storage card;
 - 25
- wherein the data read from the data storage card comprises at least one program.

- 31 -

3. An event recording apparatus for use in an automotive vehicle having at least one data generating means, each for sensing an environmental or an operation parameter of the automotive vehicle and for generating corresponding data values, comprising:
- 5
- (a) an electronic removable data storage card including non-volatile memory means for storing data, and a first serial interface means for transmitting data from the memory means and for receiving
- 10 data for storage in the memory means;
- (b) an interface adapter, adapted to removably receive the data storage card and mountable in the automotive vehicle, and including a second serial interface means for transmitting data to the
- 15 first serial interface means of the data storage card and for receiving data from the first serial interface means of the data storage card;
- (c) controller means, coupled to the interface adapter and to at least one data generating means, for
- 20 receiving data values from at least one data generating means and periodically transmitting such received data values through the interface adapter for storage in the data storage card, the controller means including means for reading data
- 25 from the data storage card;
- wherein the data read from the data storage card comprises at least one program.
4. The event recording apparatus of claim 1, 2, or 3, wherein the controller means further includes means for

- 32 -

5 enabling or disabling the automotive vehicle from operating, and wherein the data read from the data storage card comprises an expiration code in response to which the controller means enables the automotive vehicle if the expiration code is valid, and disables the automotive vehicle if the expiration code is invalid.

5. The event recording apparatus of claim 1, 2 or 3, wherein the controller means further includes means for controlling functions of the automotive vehicle in response to data values read from the data storage card.

6. The event recording apparatus of claim 1, 2 or 3, wherein the system non-volatile memory means includes one of: dynamic RAM with a battery backup and refresh circuitry; static RAM with a battery backup; flash memory; and electrically alterable read-only memory.

7. The event recording apparatus of claim 3, wherein the first and second interface means communicate over a 3-wire serial bus.

8. The event recording apparatus of claims 1, 2, or 3, wherein the non-volatile memory means includes one of: dynamic RAM with a battery backup and refresh circuitry; static RAM with a battery backup; flash memory; and electrically alterable read-only memory.

- 33 -

9. The event recording apparatus of claims 1, 2, or 3, wherein the data stored in the data storage card relates to events internal to the vehicle.
10. The event recording apparatus of claim 9, wherein the data relating to events external to the vehicle is selected from one or more of: a hazard level determined from a radar system mounted in the automotive vehicle; braking pressure; acceleration or deceleration in one or more dimensions; rate of turning; steering angle; cruise control status; brake temperature; brake line hydraulic pressure; average speed; miles-per-gallon; compass direction of travel; coolant temperature; oil temperature; engine temperature; transmission fluid temperature; engine timing; impact; tire pressure; windshield wiper status; fog light status; defroster status; and geographic positioning information.
11. The event recording apparatus of claims 1, 2, or 3, wherein the data stored in the data storage card relates to events external to the vehicle.
12. The event recording apparatus of claim 11, wherein the data relating to events external to the vehicle is selected from one or more of: the closing rate between the automotive vehicle and targets located by a radar system mounted in the automotive vehicle; the distance between the automotive vehicle and such targets; and target direction.

- 34 -

13. The event recording apparatus of claims 1, 2, or 3, further including a computer interface adapter means, adapted to removably receive a data storage card and adapted to be coupled to a computer, and including a
5 third interface means for transmitting data from the computer to the first interface means of the data storage card and for receiving data from the first interface means of the data storage card.
14. The event recording apparatus of claims 1, 2, or 3, wherein the data stored in the data storage card is normally stored at a first rate, but is stored at a second rate upon the occurrence of a selected event.
15. The event recording apparatus of claims 1, 2, or 3, wherein data storage is commenced upon the occurrence of a selected event.
16. The event recording apparatus of claims 1, 2, or 3, wherein data storage is terminated upon the occurrence of a selected event.
17. The event recording apparatus of claims 1, 2, or 3, wherein the non-volatile memory means includes multiple logical data pages for storing independent sets of data.
18. A method for recording events relating to an automotive vehicle having at least one data generating means, each for sensing an environmental or an operational parame-

- 35 -

- 5 ter of the automotive vehicle and for generating corresponding data values, comprising the steps of:
- 10 (a) providing a removable data storage card including non-volatile memory means for storing data, and a first interface means for transmitting data from the memory means and for receiving data for storage in the memory means;
 - 15 (b) providing an interface adapter, adapted to removably receive the data storage card and mountable in the automotive vehicle, and including a second interface means for transmitting data to the first interface means of the data storage card and for receiving data from the first interface means of the data storage card;
 - 20 (c) receiving data values from at least one data generating means;
 - (d) transmitting such received data values through the interface adapter;
 - (e) storing the transmitted data in the data storage card; and
 - 25 (f) reading a computer program from the data storage card.
19. The method for recording events of claim 18, further including the steps of:
- 5 (a) providing a computer interface adapter means, adapted to removably receive a data storage card and adapted to be coupled to a computer, and including a third interface means for transmitting data from the computer to the first inter-

- 36 -

10 face means of the data storage card and for receiving data from the first interface means of the data storage card;

(b) ding into a computer data stored in the data storage card.

20. The method for recording events of claim 18, wherein the data stored in the data storage card relates to events internal to the vehicle.

5 21. The method for recording events of claim 18, wherein the data relating to events external to the vehicle is selected from one or more of: a hazard level determined from a radar system mounted in the automotive vehicle; braking pressure; acceleration or deceleration in one or more dimensions; rate of turning; steering angle; cruise control status; brake temperature; brake line
10 hydraulic pressure; miles-per-gallon; fuel remaining; compass direction of travel; coolant temperature; oil temperature; engine temperature; transmission fluid temperature; engine timing; impact; tire pressure; windshield wiper status; fog light status; defroster status; and geographic positioning information.

22. The method for recording events of claim 18, wherein the data stored in the data storage card relates to events external to the vehicle.

23. The method for recording events of claim 22, wherein the data relating to events external to the vehicle is

- 5 selected from one or more of: the closing rate between the automotive vehicle and targets located by a radar system mounted in the automotive vehicle; the distance between the automotive vehicle and such targets; and target direction.
24. The method for recording events of claim 18, wherein the data stored in the data storage card is normally stored at a first rate, but is stored at a second rate upon the occurrence of a selected event.
25. The method for recording events of claim 18, wherein data storage is commenced upon the occurrence of a selected event.
26. The method for recording events of claim 18, wherein data storage is terminated upon the occurrence of a selected event.
27. The method for recording events of claim 18, wherein the non-volatile memory means includes multiple logical data pages for storing independent sets of data.
28. An event recording apparatus for use in an automotive vehicle having at least one data generating means, each for sensing an environmental or an operational parameter of the automotive vehicle and for generating corresponding data values, comprising:
- 5 (a) a data storage unit having a non-volatile memory for storing data, and means for transmitting data

- 38 -

- from the memory and for receiving data for storage in the memory;
- 10 (b) controller means, coupled to the data storage unit and to at least one data generating means, for receiving data values from at least one data generating means and transmitting such received data values to the data storage unit for storage
- 15 in the non-volatile memory, the controller means including means for reading data from the data storage unit;
- wherein the data read from the data storage unit comprises at least one program.
29. The event recording apparatus of claim 1, 2, or 3, further including a system non-volatile memory means for storing data read from the data storage card.

Abstract of WO 9418645 (A1)

In order to record accidents caused to parked vehicles, for example by other cars, the invention provides that an accident data memory installed in the parked vehicle is extended by means which, preferably after a certain time-lag after switching off the engine, maintain the accident data memory of the vehicle operative for a limited time with a sensitivity which is greater than that prevailing when the vehicle engine is switched on, in constant readiness for the detection and recording of an accident situation.

Unfalldatenspeicher

Die Erfindung betrifft einen Unfalldatenspeicher gemäß dem Oberbegriff des Anspruchs 1. Unfalldatenspeicher sind in ihrem Aufbau als solche bekannt.

Der Zweck eines Unfalldatenspeichers besteht in der Erfassung und Registrierung von Daten, die für die objektive Klärung der Schuldfrage nach einem Unfallereignis sachdienlich sind. Es ist Stand der Technik, die Bewegungsdaten sowie die Zustandsdaten einiger Fahrzeugaggregate während des Fahrbetriebs des mit einem Unfalldatenspeicher ausgerüsteten Fahrzeugs zu registrieren. Im Unfalldatenspeicher gemäß der EP 0 118 818 B1 endet die Datenaufzeichnung mit dem Fahrzeugstillstand.

Die Detektion eines Unfallereignisses erfolgt üblicherweise zumindest durch eine Auswertung der vom Unfalldatenspeicher erfaßten Beschleunigungssignale. Da Straßenunebenheiten, die normale Fahrdynamik oder das Zuschlagen einer Fahrzeugsür nicht zur Auslösung der speziell für eine Unfallsituation vorgesehenen Speicherverfahren führen dürfen, weisen die bekannten Unfalldatenspeicher Auslösekriterien auf, die die Registrierung von kleineren "Rempeleien" nicht gestatten. Wird ein parkendes Fahrzeug zB bei dem Rangiermanöver eines Fremdfahrzeugs angefahren, kann ein derartiger Unfall von den bisher bekannten Unfalldatenspeichern nicht registriert werden.

Die Aufgabe der vorliegenden Erfindung ist es, diesen Nachteil zu beseitigen. Sie wird durch die kennzeichnenden Merkmale des ersten Anspruchs gelöst. Die weiteren Ansprüche zeigen vorteilhafte Weiterbildungen.

Erfindungsgemäß wird vorgeschlagen, zusätzlich zu den während des Fahrbetriebs erforderlichen höheren Ansprechschwellen für die Auslösung der speziell zur unlöschbaren Registrierung einer Unfallsituation vorgesehenen Speicherverfahren Mittel

vorzusehen, die die Betriebsbereitschaft des Unfalldatenspeichers nach dem Ausschalten des Antriebsaggregats des Fahrzeugs für eine begrenzte Zeit mit einer erhöhten Empfindlichkeit für die Detektion und Registrierung von Unfallereignissen fortzusetzen.

Die Erhöhung der Empfindlichkeit kann dadurch erfolgen, daß der zur Auslösung der Unfallregistrierung festgesetzte Schwellwert der Amplitude der Beschleunigungssignale um etwa 90 % herabgesetzt wird bei gleichzeitiger Verlängerung des Betrachtungszeitraums der zur Auslösung führenden Einwirkungsdauer des Beschleunigungssignals. Dadurch, daß der Unfalldatenspeicher mit Mitteln zur Durchführung dieser Maßnahme erweitert wird, werden am geparkten Fahrzeug auch leichte Stöße detektierbar.

Um Fehlauslösungen zu vermeiden, ist eine Umschaltung des Unfalldatenspeichers auf diese erhöhte Empfindlichkeit nur bei stillstehendem Fahrzeug sinnvoll. Zur Steuerung der Umschaltung benötigt der Unfalldatenspeicher die Information darüber, in welchem Betriebszustand sich das Antriebsaggregat des Fahrzeugs befindet. Diese Abfrage erfolgt vorzugsweise über eine Erfassung der Schaltstellung des Zündstartschalters des Fahrzeugs.

Um Fehlauslösungen unmittelbar nach dem Ausschalten des Antriebsaggregats des Fahrzeugs zu vermeiden, die beispielsweise durch das Verlassen des Fahrzeugs durch die Fahrzeuginsassen oder das Entladen des Fahrzeugs hervorgerufen werden könnten, empfiehlt es sich, die Umschaltung auf die erhöhte Empfindlichkeit zeitverzögert durchzuführen. Eine Verzögerung von ca. 5 Minuten erscheint im allgemeinen praxisgerecht. Dadurch kann sichergestellt werden, daß sich das Fahrzeug in Ruhe befindet.

Um ermittlungsdienliche Aussagen zum Unfallereignis machen zu können, ist es vorteilhaft, den erfindungsgemäß erweiterten Unfalldatenspeicher mit Zeitzählmitteln auszustatten, so daß der Unfallzeitpunkt genau bestimmt werden kann. Die

Zeitzählmittel können in einer als vollständiges Kalendarium ausgebildeten Echtzeituhr oder nur aus einem Relativzeitmesser bestehen. In jedem Fall kann auf diese Weise zusätzlich zu den durch die Beschleunigungssignale erfaßten Stoßdaten eine Zeitmarke in dem registrierten Datensatz abgelegt werden.

Patentansprüche

1. Unfalldatenspeicher
 - a) mit Mitteln zur Erfassung von Beschleunigungssignalen,
 - b) mit Mitteln zur Analyse der erfaßten Beschleunigungssignale hinsichtlich ihrer Amplitude und ihrer Einwirkungsdauer für die Detektion einer Unfallsituation,
 - c) mit Mitteln zur Abfrage des Betriebszustandes des Antriebsaggregats des Fahrzeugs, in welchem der Unfalldatenspeicher installiert ist, und
 - d) mit Mitteln zur Speicherung der erfaßten Signale und/oder der daraus ermittelten Daten,gekennzeichnet durch Mittel, die den Unfalldatenspeicher nach dem Ausschalten des Antriebsaggregats des Fahrzeugs für eine begrenzte Zeit mit einer gegenüber dem Zustand des eingeschalteten Antriebsaggregats erhöhten Empfindlichkeit in einer fortdauernden Bereitschaft für die Detektion und Registrierung einer Unfallsituation aktiv erhalten.
2. Unfalldatenspeicher nach Anspruch 1, dadurch gekennzeichnet, daß die Erfassung des Betriebszustandes des Antriebsaggregats des Fahrzeugs durch eine Abfrage der Schaltstellung des Zündstartschalters erfolgt.
3. Unfalldatenspeicher nach Anspruch 1 oder 2, dadurch gekennzeichnet, daß die Umschaltung in die erhöhte Empfindlichkeit für die Detektion und Registrierung einer Unfallsituation zeitverzögert nach dem Ausschalten des Antriebsaggregats des Fahrzeugs erfolgt.

4. Unfalldatenspeicher nach Anspruch 1, 2 oder 3, dadurch gekennzeichnet, daß die nach dem Ausschalten des Antriebsaggregats des Fahrzeugs fortdauernd betriebsbereiten Mittel zur Detektion und Registrierung einer Unfallsituation zur Registrierung des Zeitpunktes eines Unfallereignisses mit Zeitzählmitteln ausgestattet sind.

(54) Title: ELECTRONIC VEHICLE LOG

(57) Abstract

A method and apparatus for maintaining an electronic vehicle log (1) involves the formation of protected data packets (411) which are electronically signed by certified users. The electronic vehicle log (1) preferably comprises a secure non-volatile memory (2) that may be removed from the vehicle (200). Preferably the apparatus, referred to herein as a data processing interface unit (DPIU) (1), has access to date and real time of day and location data so that the protected data packets (411) further include, besides data to be protected, the date and time of day and the location of the vehicle (200) for comparison with expected data as further protection against fraudulent or forged data entry. Preferably, on-board sensors (6) collect in-transit monitoring and cargo monitoring data for access by various certified users. Event data such as governmental inspection or border crossing data may be entered into the log by governmental authorities.

ELECTRONIC VEHICLE LOG**BACKGROUND OF THE INVENTION****1. Technical Field**

This invention relates to the field of electronic vehicle logs used particularly in commercial vehicles and, more particularly, to a data collection and processing system for a vehicle serving multiple users including the driver, the owner/operator and governmental authorities. Even more particularly, the invention is directed to securing access to particular data by such users via the application of evolving "smart" or "flash" card, public key/private key encryption and electronic signature, speech recognition and speaker verification and global positioning or other navigation system technologies.

2. Description of the Related Arts

Many vehicles, particularly those used commercially, must maintain legally auditable records of their usage. These records may include and not be limited to include data items such as license or registrations issued, insurance coverage, the routes traveled, gross and tare (cargo exclusive of container and vehicle) weight measured at weigh stations, driver and duration of driving, safety inspection results, border crossing approval, exhaust pollution measurements and the like. In addition to vehicle related items, additional data may be required concerning the cargo and any tariffs or other fees paid on that cargo. Other records may also be required or used by the driver, the owner/operator (if different), and governmental authorities or agencies.

For the purposes of the present application, vehicle credential data is defined as data describing the vehicle, the carrier, cargo, driver, and passengers independently of the transit involved. Vehicle credential data may thus include the following data, the following list being exemplary of such data: vehicle registration, vehicle insurance, driver's license, driver's credentials, driver's safety record and health, cargo manifest and shipping invoice, tariff-related documentation, and declared itinerary or intended route data.

In-transit data is defined for the purposes of the present application as data obtained during transit or in route (whether the vehicle is in motion or not). Such data may be acquired by periodically monitoring sensors on the vehicle to determine how the vehicle is being used. Exemplary data falling into this category of data

include: date and time of data collection, vehicle speed, brake usage, steering wheel motion, engine RPM, engine temperature, cargo container temperature, engine vibration and other health metrics, and vehicle location from a navigation source such as the so-called Global Positioning System (GPS) or equivalent data gathering system.

5 Cargo monitoring data is defined for the purposes of this application as data related to either the status or security of the cargo, for example, whether the cargo seal has been maintained or broken.

 Next, event record data is defined for the purposes of this application as data recorded in transit for particular events effecting the vehicle or cargo or both.
10 Typical events include: vehicle weight, for example, obtained during a weight-in-motion or stationary scale weighing, vehicle environmental, emissions or safety status checks, for example, determined at an inspection facility, border crossing data, either state or national, hazardous material (HAZMAT) warnings or transit regime changes (when the vehicle starts motion or has stopped).

15 Finally, route monitoring data is defined for the purposes of the present application as data obtained through monitoring the vehicle in transit to compare with the above-defined vehicle credential data for an intended route. This data is preferably collected through the application of a navigation system such as GPS or other equivalent system as well.

20 Typically in the past, such records, if maintained at all, have been manually maintained in a handwritten log or plurality of such logs, augmented by inspection records from various agencies or authorities and maintained by the driver. However, such handwritten logs are inherently subject to inadvertent inaccuracies, as well as to intentional fraud or forgery. In addition, such handwritten records cannot be easily
25 transferred for inspection.

 Ebaugh et al., US Patent No. 5,303,163, describes a configurable vehicle monitoring system having first and second configuration levels for an owner/operator and a driver respectively. Besides being able to independently configure data in memory, each is independently able to access certain data of interest to that party
30 alone. The data that can be gathered and analyzed includes miles per gallon, fuel consumed, trip time, idle time, fuel consumed and other pertinent information relevant to fleet or vehicle operation. For example, according to Figure 7 thereof,

a printout may be obtained showing these and other data. The owner/operator may obtain an indication of the period of time the vehicle is operated in excess of the 65 mile per hour overspeed limit. Similarly, apparatus disclosed by Ishibashi, US Patent No. 5,379,219, and Komatsu, US Patent No. 5,249,127 suggest the tracking of speed over time and, per Figure 3 of the '219 patent, the allocation of memory among ID data, speed data, travel distance data and optional area. The '127 patent suggests that, memory size requirements being indeterminate and expensive, data compression devices be provided for assuring efficient utilization of memory.

It has further been recognized that portability of the collected data is required. One means of achieving portability is via an external memory module (US 4,757,454, 5,185,700 or 5,249,127). Also, radio or generally wireless radio communication may provide data mobility from one user to another (US 4,804,937, 5,185,700 or WO 90/09645).

The so-called global positioning system described, for example, by Taylor et al., US Patent No. 4,445,118 and O'Neil et al. US Patent No. 4,839,656 has been implemented in an electronic vehicle log by Haendel et al., US Patent No. 5,359,528. Haendel et al. describe that a change in state boundary and a log of miles within a particular state may be automatically obtained without driver intervention.

All of these systems suffer from a lack of security of access by a particular user and may be falsified if and when the provided weak security systems fail. It is an object therefore of the present invention to describe a system whereby multiple users of a system may configure or obtain access to memory of an electronic vehicle log. It is a further object of the present invention to provide a system wherein security is enhanced via adaptation of evolving technologies of speech recognition and speaker verification, public/private key data encryption and decryption, flash or smart card (key) access and/or electronic signature record verification and access.

SUMMARY OF THE PRESENT INVENTION

In accordance with the present invention, an electronic vehicle log (EVL) comprises a processor for processing data, a memory for storing software algorithms and fixed data, preferably non-volatile in nature, a secret key unique to the vehicle log, and a unit serial number that is unique to that unit (hereinafter, an EVL identifier), a removable non-volatile log memory for securely recording data and a

navigation and time-of-day and date input data circuit. In one embodiment, there may be further provided a microphone input for receiving user speech coupled to the processor (for example, via an analog to digital converter) and a memory for storing digitized voice samples. Optional sensors are coupled to the log for providing for the
5 input of data for vehicle and cargo, for example, through an external interface, in particular, a wireless interface. For example, through one external wireless interface, an EVL may acquire event data such as weight-in-motion (WIM) data. Those who would obtain access to data or input data are provided with a public key which is likewise unique to the vehicle log. Moreover, any data entries are signed with an
10 electronic signature for verifying the entered data, for example, comprising a calculated hash value encrypted with the secret key.

When the vehicle is to be used, the driver inserts the removable non-volatile log memory for the duration of the trip. For example, a driver may obtain access and log into the EVL by inputting their speech, a password or a biometric after
15 inserting their card memory. Upon successful verification of the password or biometric and, if appropriate, verification of the speaker's identity in a well known manner, the driver-unique data is used to decrypt a secret key member of a public key encryption pair. When data is to be logged by the driver, protected data packets (PDP's) containing this log data are generated with digital signatures formed by
20 encrypting digital hash values with this secret key member of the public key pair.

Protected data packets (PDP's) are transmitted to a requesting user via electronic means, for example, wireless, telephone modem or a memory card. The requesting user has a trusted (escrowed) copy of the public key of the above-referenced public key pair, the public key pair including the secret key (securely
25 stored in and never released from EVL memory) used for forming the electronic signature. The secret key should be protected and secured as closely as possible and should not be transmitted (otherwise, it might be intercepted by an uncertified individual). The public key is used to verify that the electronic signature of the PDP is accurate. Correct verification of the electronic signature then confirms the data
30 source (the driver-protected secret key) and the integrity of the data (since the hash value matches the PDP data).

A governmental authority may obtain access by a defined process. One

example of such a process for obtaining an early transmission of vehicle data in advance of a border crossing or like event is described by the following. The agency wishing to receive secure data generates a public key encryption pair different from that used by the driver and distributes the public key portion to any person or system desiring to transmit secure data. The public key portion is stored in EVL memory. A profile of a commercial vehicle and a cargo may be extracted from the vehicle via a card memory or may be electronically extracted by wireless means prior to the vehicle's departure and delivered to the authority with the stored public key portion. The EVL generates a private encryption key and uses it to encrypt PDP's with their corresponding digital signatures. The EVL encrypts this private encryption key using the public key and transmits that information to the agency receiving the data. The receiving agency decrypts the EVL private encryption key using the secret key portion of the key pair and then decrypts the PDP's using the decrypted key. The profile and public key are transmitted via a centralized authority data base to regional data bases for distribution to checkpoints, port of entry border crossings and the like along the intended route of the vehicle.

As the vehicle approaches the inspection facility, the vehicle is polled or interrogated, for example, preferably by wireless means in advance of reaching the facility, so the vehicle need not stop its movement. The vehicle transmitted profile data is compared with the previously transmitted profile data and the inspector may preclear the vehicle through the inspection station. If the inspection data is a weigh station, for example, and data is to be entered into the log by the authority, an electronic signature is utilized to verify the entered data, preventing subsequent modifications of the logged information. Moreover, at the time the entry is made, the vehicle position and time from the global positioning system may be automatically and simultaneously recorded, allowing detection of fraudulent entries. As the vehicle crosses the border, a short range communications system may be used to verify that the vehicle crossing the border is the vehicle which received the preclearance to cross.

It is also possible that the vehicle may carry all the profile information in the EVL and transmit the data via wireless means to the authority just a few minutes before the approval (for example, preapproval at a border crossing) event. In this

case and in that described above as well, some sort of short-range transmission is useful as the vehicle crosses the border to physically confirm that the vehicle currently crossing the border is the same as the one that provided the profile and credentials and received preapproval to cross.

5 An authorized individual such as an inspector or police officer creates a digital credential in a generating device's memory, for example, a laptop personal computer. A secret key of a public key pair is used to generate a digital signature for the credential data. The credential and signature are transmitted to the EVL using various means, possibly including wireless means, direct input (typing), or memory
10 card transfer. This transfer may be encrypted as discussed above as desired. for wireless or other secure data transmission. The credential and signature are formed into a PDP and logged as described above for the driver data logging operation. When the credential is subsequently transmitted to a requesting agency, the agency will use a trusted copy of the public key portion to verify the electronic signature of
15 the PDP.

Other features and advantages of the present invention will be explained by reference to the drawings and the following detailed description of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

20 Figure 1 is an overview drawing of an electronic vehicle log according to the present invention;

 Figure 2A is a system overview drawing showing the interface between a vehicle 200 carrying an electronic vehicle log of Figure 1 with a governmental or other authority and Figure 2B shows vehicle 200 with expanded boxes describing data
25 that may be stored in DPIU 210 including an electronic vehicle log of the present invention;

 Figure 3 is a schematic block diagram of the electronic vehicle log of Figure 1 for maintenance in a vehicle; Figure 3A provides a first embodiment, Figure 3B provides a second embodiment and Figure 3C provides a third embodiment;

30 Figure 4A provides an overview of the key and security features of the present invention in flow diagram form and Figure 4B shows a table showing the use of different public key pairs by different entities for accessing the data stored in the EVL

400 of Figure 4A;

Figure 5A provides a table of examples of data maintained in an in-vehicle data base of memory of the in-vehicle unit of Figure 4; Figure 5B comprises a table showing data elements and characteristics recoverable through utilization of the present invention and their characteristics; and

Figures 6A and 6B provide a table showing service, application, technology or product availability, demonstrable feature and utilization of the present invention.

DETAILED DESCRIPTION OF THE PRESENT INVENTION

Referring to Figure 1, there is shown an overview drawing of the electronic vehicle log of the present invention. The present device is intended to be placed in a vehicle, hence, the present invention is described herein as an in-vehicle data processing unit. The log is described herein as electronic because it generally operates via electronic circuits including at least memory circuits and a data processor. The present invention is characterized as a log because the memory of the present invention substitutes for prior art hand-written log books typically used by drivers of vehicles, especially commercial vehicles.

The electronic vehicle log (EVL) 1 is described by box 1a as comprising a package of elements suitably housed to be mounted in a vehicle, for example, in an operator compartment or secure area therein or proximate thereto. One mounting arrangement would be to provide a bracket mounting plate permanently secured to the vehicle. The EVL housing, herein referred to as a data processing interface unit (DPIU) then is removably secured thereto by mechanical locking apparatus so that the DPIU may be removed from the vehicle as necessary. The mechanical locking apparatus should be tamper-resistant so that the EVL itself cannot be surreptitiously moved from one vehicle to another without detection. (To accomplish this objective, electronic tamper detection may be employed). Preferably, the DPIU housing is adapted to receive a removable security module as will be further described herein which is the electronic vehicle log itself.

The EVL housing 1 (DPIU) contains a processor, preferably a microprocessor and a non-volatile memory coupled thereto for storing at least secret key data, secret EVL unit serial number data and executable software. The EVL 1 further may comprise a random access memory that typically is volatile for storing data on a

temporary basis and a real time clock (typically a software algorithm that is preferably periodically updated). Most processors require a clock oscillator output that is controlled for providing processor operation clocking functions. This clock can provide a clocking input to a real time clock algorithm as is well known in the art. However, for greater security, an independent clock source may be used or an internal isolated hardware clock circuit (not shown). A navigation system such as the Global Positioning System (GPS) or Loran or other system can provide the independent clock source or periodic indications as to true time for synchronizing a local real time clock as is likewise known in the art. Of course, another important function of GPS or other known equivalent systems is the provision of periodic location data in the form of earth latitude and longitude data and even altitude data that may be compared with a map or intended route and thus provide specific data as to real time of day and route location. A further description of preferred embodiments of EVL 1 will be provided in connection with applicant's description of Figure 3.

EVL housing 1 has insertable therein a removable non-volatile memory module 2 described by box 2a which becomes the log in place of known paper logs or other known electronic logs. In accordance with the present invention, the log memory 2 stores secured or protected data packets output from the EVL included processor as will be further described in connection with Figure 4.

The EVL 1, according to the present invention, may communicate with governmental authorities via radio 3, according to box 3a which may be optional or through wired or other means. Certainly by radio is intended communication via all radio frequencies including light frequencies or via laser or other known means that is wireless in nature. As will be further described herein in the example depicted in Figure 2 of a border crossing, the EVL communicates with an inspection facility for border preclearance before reaching the border via wireless means, so the vehicle need not stop.

The EVL 1 may be provided with a display or other output means 4. The display, as indicated by descriptive box 4a, may be optional. The display may comprise a liquid crystal display, cathode ray tube display, light emitting diode or other display. Other output means may comprise a printer or speech synthesis means

or other output means. All such means provide the user (typically the vehicle operator) with feedback of proper operation, an indication that the vehicle is being polled, clearance to proceed, log data, if appropriate, and other information.

5 Controls 5, as described by box 5a, are likewise optional. The controls typically comprise a keyboard, keypad or related switch control but may comprise
5 speech receiving means 7 described by box 7a as a microphone such as an electret microphone or digital microphone. Also, both keys and microphones may be provided. The microphone may be eliminated if speech input is not contemplated by one designing a system according to the present invention. The controls may be keys
10 representing, for example, numeric or alphabetic characters for inputting the operator's identity, password or other data as will be described further herein. If necessary the microphone is coupled to the processor of the present invention via an analog to digital converter for sampling the voice input and converting the input to digital samples.

15 Finally, in accordance with Figure 1, sensors 6 may be provided which are only generally described. These may comprise brake sensors, accelerator sensors, tachometer or mileage sensors, speedometer sensors, steering column sensors, tire pressure monitoring sensors, cargo bonding sensors, cargo temperature or smoke or fire sensors, driver alcohol (breath) detection sensors and the like which may be
20 coupled to EVL 1 by wired or wireless means.

In-transit, cargo and route monitoring data use sensors which are preferably mounted on the vehicle and locally communicate with the EVL using fixed communications channels (cabling or short-range radio signals). Credentials and event data recording typically requires acquiring data from systems separate from the
25 EVL housing 1 which are not permanently mounted on the vehicle. For example, a customs agent may be empowered to record a credential within the EVL which indicates that paperwork is in place and tariffs paid to allow expedited international or state border crossings as will be described further in reference to the example of Figure 2. This credential information is placed within the EVL by any number of
30 transmission methods and via security means including direct entry, via a removable credential memory, via direct connection and via radio connection.

In regard to direct entry, the EVL 1 may provide a keyboard and limited

display for manual entry of the information. This may be relatively tedious and insecure. The entry process may include the agent (inspector) specifying an encryption key, either public or private, which may be used in a signature process for authenticating entered data. The process may involve speech recognition and voice entry of the data in combination with a keyboard/display or alone. The process may further comprise speaker identification or verification processes known in the art for confirming a subject's claimed identity based upon a digitized speech sample.

Removable credentials are preferred. If the EVL memory is removable, it may be placed in a data entry device belonging to the agent and the electronic credential or event data copied into the memory. When the memory device is replaced into the EVL 1, the newly acquired data will be processed as a normal PDP as described below in connection with Figure 4.

Direct connection may be cumbersome. The EVL may be directly cabled to the agent's data entry device, using a media such as an RS 232 serial data channel or equivalent serial or parallel connector. Data processing in this case is comparable to that when using removable credentials.

Finally radio connection may be preferable for, for example, coupling to mobile police forces, air such as helicopter carrying radio, or roadside radio polling stations so the vehicle may transmit in motion. Radio may be used to receive or transmit credential and event data. One example is a weight in motion (WIM) station operated by a governmental authority. A WIM sensor may, when interrogated by the EVL, transmit the vehicle's weight to the EVL for storage.

As will be further described in connection with Figure 2, an agent uses a personal computer or workstation to generate, for example, border crossing or inspection credential data. An agent-specific secret key is used to embed their electronic signature within the credential data transferred to the EVL 1. Thus, the data may not be accessible to the driver or even the vehicle system operator. When the credential data is later transmitted to an authorizing agent (such as the border crossing inspector), the corresponding public key is used to decrypt the signature, thereby authenticating the source and permitting preclearance of the vehicle.

Now, referring to Figure 2, one application of the present invention will be described, namely a border crossing, to demonstrate the interrelationships among the

elements of Figure 1 which may be assembled in combination to perform any desired application of the present invention. Figure 2 generally represents in diagrammatic form the events at a border crossing of a vehicle 200 equipped with the EVL 1 (Figure 1) of the present invention (represented as box 210). Other applications will be described subsequently herein. Vehicle 200 may be a truck, for example, 5 approaching a border crossing 202 which may be a state or international border along a route 201. There are three zones of route 201 the vehicle 200 is expected to pass through. Zone 205 comprises a reporting zone. Zone 206 comprises an evaluation/clearance zone. Zone 207 comprises an inspection zone for performing a detailed inspection, as necessary, of vehicle 200 or health check of the vehicle's driver. The arrows on route 201 indicate the expected direction of passage of vehicle 200. 10

Referring briefly to Figure 2B, there is shown a typical vehicle 200 and blocks 261-266 summarizing data that may be related thereto. Block 261 describes motor vehicle data such as ID number, EVL or DPIU identification number and status, 15 vehicle weight and registration data. Driver data 262 comprises their identification, their licenses, safety record, transit log and safety biometrics among other data. Carrier data 263 includes identification, location, registration, insurance, licenses and permits, ICC, PUC, USDOT records, violations and offenses and fees paid records. 20 Cargo data 266 includes trailer identification, invoice, manifest, HAZMAT warnings, gross and tare weight, export declaration, inspection record, tariff record and crossing approval data. Together, these data 261, 262, 263 and 266 may be vehicle credential data as used in the context of the present application.

Transit security block 264 refers to electronic bonding data, route verification 25 data and time-in-travel verification data.

Safety and environmental data block 265 refers to a combination of event data and in transit data. In particular, block 265 refers to inspection records, emission records on-board sensor records and HAZMAT warnings.

Typically at a border 202 or proximate thereto is an inspection facility 203. 30 At the inspection facility, work stations, shown as computer workstations, 204 are provided governmental employees, such as inspectors. The work stations and/or inspection facility 203 preferably communicate with vehicle 200 which may be

moving by wireless means. The PC-based inspector workstations 204 are described by box 220. The workstations function to interface with an interface unit described by block 210 usually referred to herein as the EVL of vehicle 200 and to roadside sensors of a polling station (not shown). These sensors respond as a vehicle passes a polling station in motion to obtain data from the EVL. These may not need be "roadside" but may be "fly over" and thus mounted in aircraft such as helicopters or other traveling vehicles such as police vehicles. In any event, the workstations 220 function to record electronic credentials either downloaded in advance or provided from the EVL 210 of the vehicle 200. The workstation 204 may interface with centralized databases to obtain data that is not stored in the workstation as necessary. Finally, it is desirable if the workstations 204 are networked together for intercommunication and interchangeability. That is, if one workstation is occupied, a first spare workstation is allocated to an new incoming vehicle 200 to the system.

The work stations 204 and/or inspection facility 203 generally are provided with an EVL interface unit for interfacing with the in-vehicle EVL 1 of vehicle 200. The functions of this interface unit are described by box 210 which couples the inspection facility 203 or workstation 204 or both with the EVL resident in vehicle 200. This interface unit carries and provides credentials/manifests/inspection records collected for a vehicle. The interface unit also collects multi-sensor reports from on-board sensors on the commercial vehicles such as vehicle 200, for example, on odometer readings, brakes, cargo bondings and the like as optionally provided. Moreover, the interface unit provides vehicle to roadside (or fly over) polling stations communication between the EVL and the governmental employees such as inspectors and inspection stations such as weight-in-motion measuring stations. The latter data may be recorded in the EVL as will be described in connection with Figure 4 as protected data packets. Another function of the interface unit is general information management and the updating of the EVL data base and records due to governmental activity. For example, the opportunity for preclearance of a vehicle through an inspection station is one type of data that may be entered into the EVL. Finally, the interface unit provides electronic security in accordance with the security features described by Figure 4. Communications to and from the vehicle 200, especially if wireless, are preferably secured from interception by coding and/or encryption as

desired.

In operation, a vehicle 200 moves along route 201 into a reporting zone 205. The vehicle 200 may initiate radio contact with inspection facility 203 or the vehicle may be polled via roadside or other monitors. Meanwhile, manifests for the vehicle and associated data are preferably electronically downloaded by a broker (a carrier or other party) for storage at the facility 203. Current manifests of expected vehicles are provided to individual inspector workstations 204. Responsive to a polling signal or associated with a request for preclearance initiated by the vehicle, the vehicle data of particular vehicle 200 is provided via wireless means to inspection facility 203 and compared at workstations 204 with downloaded data, such as manifest data. On-board the vehicle, the driver may be provided with a display indicating the EVL is being monitored and thereby reported to him. Moreover, a report or record of the monitoring activity may be stored in the EVL along with a real time of day and location indication as will be subsequently described herein.

The vehicle then enters an evaluation/clearance zone 206. The governmental authority such as an inspector assesses the records/data obtained from the EVL at his workstation 204. If the inspector is satisfied, the inspector communicates a bypass or, if not satisfied, a no-go signal to the truck. Of course, the EVL records and updates itself according to the bypass or no-go signal. As the vehicle approaches the border 202, roadside monitors may poll the vehicle in transit as it crosses the border to assure that the vehicle crossing the border is in fact the vehicle given preclearance to cross. There exists the possibility that preclearance may not have been received in a timely manner even though preclearance could have been granted as the vehicle enters the inspection area 207. Vehicles not receiving timely preclearance and vehicles whose credentials are suspect may be signaled to stop in inspection zone 207.

As the vehicle 200 moves it will enter a detailed inspection area indicated as such on route 201. Inspection zone 207 corresponds thereto and, at the area, a detailed inspection of vehicles which fail or do not timely receive preclearance occurs. Vehicles which may not receive preclearance (not permitted to bypass the station) may include those providing a cargo bonding breakage signal, an indication of improper or errored credentials or manifest data and the like or presenting safety issues such as faulty brake or related signals. Whether or not monitored, driver

health issues may also be checked (for example, vision or drug/alcohol levels). The inspections may be random, i.e., ordered as a result of proper data reporting but nevertheless a no-go signal is signaled to the particular vehicle 200. If the vehicle safety, driver health or driver safety (overspeed or erratic activity) are signaled as problematical, each of these in turn may be checked or inspected.

Thus, as described above, an embodiment of the present invention may provide for a vehicular data processing method for use by a vehicle in crossing a border comprising the steps of initiating a request for preclearance or automatically receiving a polling signal; responsive to a polling signal, transmitting at least vehicle credential data; and receiving a bypass signal or a stop signal, the bypass signal indicating that the vehicle may pass and the stop signal indicating the vehicle must stop. Preferably the data is transmitted in a secure manner as will be further described in connection with Figure 4. Other related methods that will be further described herein include the automatic monitoring of safety equipment, driver credential, driver health or driver safety by police, the automatic monitoring of cargo bonding devices and cargo temperature, cargo weight, tariff payment and the like.

Now referring to Figure 3A, there is shown one alternative embodiment of an electronic vehicle log according to the present invention. A further embodiment is described by Figure 3B and yet a third embodiment is described by Figure 3C. From a study of each embodiment, one of skill in the art will be prepared to design an electronic vehicle log for a particular application and/or vehicle type and, in accordance with Figure 4, design an appropriate security method and means depending on the level of security desired.

Figure 3A shows an in-vehicle data processing interface unit. Box 300 exemplifies a housing for housing components of an EVL according to the present invention. The EVL system apparatus 300 includes, for example, a radio or other vehicle-to-roadside, vehicle-to-vehicle or vehicle-to-aircraft communications apparatus 301. Examples of short range devices that may be used include a Hughes Radio or Mark IV (MkIV) units or other similar radio systems known in the art or so-called automatic vehicle identification units. Longer range communication may be cellular radio via telephone modem or 220MHz radio manufactured by Scientific-Atlanta and other suppliers. Also, Qualcomm Omnitrac provides longer range communications.

Apparatus 301 is coupled between a suitable antenna (via link 309) and computer processing unit 302. Similarly situated is systems applications apparatus 303 for, for example, receiving GPS or Loran or other location and time update data via an antenna via link 310. Other functions of apparatus 303 include security and built-in-
5 test (BIT) test circuitry. Processing set 302 and systems applications apparatus 303 may be powered by the vehicle battery via a 12-volt power inverter or other circuitry 304. Computer processing set 302 houses the processor, non-volatile (software algorithm) memory, PCMCIA (card or module) receiver, analog/digital interfaces as necessary, operator/machine interfaces as necessary and built-in test circuitry. The
10 plug-in security EVL module is represented by both 307a and 308a for storing fixed and variable data respectively via respective links 307 and 308. Fixed data 307a of an EVL includes and should not be considered to be limited to include cab identification data, truck line identification data, registration data, location data and the like. Variable data 308a may be considered to include and not be limited to
15 include driver identification data, trailer identification data, load identification data, route data, initial weight data, credentials and fees data, hazardous material data and safety inspection data.

Of course, one purpose of the device 300 and log 307a, 308a is to provide via antenna(s) 309 certain outputs 310a responsive to certain external inputs 309a. Inputs
20 309a comprise the polling request and the identification of the poller. Once the polling request is made, data returned and authorization determined a preclearance authorization signal is another input. Yet another input may be a request to stop for a detailed inspection as has been already described above that may be an alternative to a preclearance authorization signal. The outputs 310a, typically provided in
25 response to a poll, comprise the identification, classification and location of the vehicle and driver. As necessary, a preclearance request signal may be generated. Other credentials necessary for polling site preclearance are provided as necessary. The safety/health of the vehicle/operator may be output. Also, there may be provided a mileage and fuel report for purposes of comparing with intended route and typical
30 fuel consumption figures.

Processor 302 is linked to on-board sensors via link 305 which may be wired or wireless. Vehicle sensor data 305a comprises driver condition data (for example,

alcohol sensors for intoxication determination), load condition/security (temperature, bonding), vehicle condition (engine temperature)/security and the like and internal data processing unit security sensing (the BIT test) among others too numerous to list.

Processor 302 is also linked, for example, as necessary to alternatives to
5 known short range roadside polling devices via known in the art systems described above such as automatic vehicle identification systems. These devices return data to the inspection facility responsive to inspection facility initiated polling requests by alternative means.

Thus, there is provided apparatus for maintaining an electronic log of
10 vehicular activity for an automatic border crossing comprising radio apparatus for communicating with an inspection facility and for periodically receiving time and location data. Protected data packets as electronically signed and stored in variable data EVL 308a as will be described in connection with Figure 4.

Yet another preferred embodiment of an in-vehicle unit is shown in Figure 3B.
15 While the whole of Figure 3B is labeled as an Electronic Vehicle Log, Figure 3B is similar to Figure 3A in that box 350 represents a housing in which are situated elements including a processor and memory and connections are shown to other elements outside the housing such as the EVL log media 370 preferably comprising a disk, flash memory, card or other NVM. For simplicity, Figure 3B does not show
20 a microphone, all the optional sensors, the antennas for wireless communication and the like shown in Figures 1 or Figure 3A.

In particular, within box 300 are a bus system 356 for coupling various
circuits together and providing intercommunication at a sixteen bit level such as an International Standards Authority (ISA) standard bus system known in the art. The
25 ISA bus 356 provides 16 bit data lines and 24 bit address lines for addressing and retrieving data from memories connected thereto. Connected to the bus 356 are a processor 351, a PCMCIA controller 352, a flash memory 353, a volatile memory 354 and an interface controller such as a quad serial interface controller 355. Sample capacities, not intended to be limiting the present invention, are 512 kbytes for
30 volatile memory 354 and flash memory 353.

Processor 351 provides the intelligence for the unit and may comprise, for example, an ELAN 80386 integrated processor or other microprocessor. The "386"

processor has internal random access memory and program memory which may be insufficient for the present purposes. Consequently, external flash memory 353 and volatile memory 354 are provided for providing sufficient capacity for the tasks at hand. Flash memory 353 is non-volatile and may store fixed data such as the unit
5 identification, algorithms and the like in permanent secure form. Volatile memory preferably random access memory provides working space for processor 351.

Controllers 352 and 355 provide slave control of input/output functions for the processor 351. PCMCIA controller 352 is coupled to the EVL credentials non-volatile memory 370 which may be in the form of one or more disks, flash memories,
10 smart cards or other like removable secure memory which may be inserted into yet another processor (personal computer, mainframe, or like computer) for loading credential data prior to vehicle departure.

In particular, credentials may be inserted briefly into the PCMCIA slot, read into EVL volatile memory, and the credentials then removed freeing the slot.
15 Alternatively, the credentials may be left in the EVL during the entire transit. In this case, the log may be placed on the same physical device as the credentials, or the spare PCMCIA slot 390 may be used as the EVL log memory device.

Controller 352 also handles input functions from a global positioning system card 380 known in the art. This card may be coupled to an antenna for periodically
20 receiving real time of day and location data and storing the data in buffer memory for use by processor 351 for forming protected data packets as will be further described herein. The card may be clocked by a local oscillator and have an internal real time of day clock algorithm which is periodically maintained at a correct time of day by a satellite downlink signal received at an antenna (not shown).

25 Controller 352 also interfaces with a spare card that may be used for storing credentials, may comprise an analog interface or an interface to another bus system such as a vehicle bus system for collecting vehicle data (engine temperature, ignition, oil, fuel consumption, odometer and the like). The PCMCIA card 390 may have other applications which come to mind from a further study of the present invention.

30 Finally, controller 355 provides a plurality of, for example, RS232 serial line interfaces to, for example, digital cellular communications apparatus or Type 3 AVI tags for roadside-to-vehicle short range communications via link 395, to other

wireless communications via link 396, to additional sensors, such as digital sensors via link 397 different from those supported by card 390 and/or accessible through a vehicle bus and to a user interface via link 398 such as a keyboard, speech interface and/or display or speech synthesis interface.

5 These elements together perform the following functions. The processor 351 provides overall processing control and includes the internal capabilities to control two PCMCIA ports on its own, namely ports for PCMCIA cards 360 and 370. One (the EVL media or card 370) has already been described. The other is analog acquisition card 360 providing eight connections each for continuous and discrete
10 analog signals, with the continuous signals typically digitized to 8 or 12 bits of resolution, for reception of such vehicle data as ignition switch position, speed, steering, brake accelerator data, tachometer data, electronic cargo bonding data and the like.

 Some processors 351 desirably provide on-board One Time Programmable
15 (OTP) memory which may be used to securely record the EVL-unique secret key and identification number. These are most desirably maintained as closed to the function of forming protected data packets as possible and desirably are not removed to FLASH memory 353 for fear of being intercepted and known by one not intended to possess them.

20 The FLASH memory 353 then is more desirably used for permanently storing the executable software. The memory 353 may be loaded at the time of manufacture with the EVL-unique secret key and identification number if that data is not included in the processor's (351) on-board OTP memory. All memory capacities, bus sizes, capabilities and speeds are nominal. For example, the unit may provide DRAM and
25 FLASH memory sizes from 256 kilobytes to 1024 kilobytes or larger by utilizing alternate sized chips currently available. Currently available PCMCIA analog acquisition cards provide four to eight channels each of continuous or discrete inputs, but higher densities are anticipated and can be incorporated without changes to the unit's (300) hardware. Flexibility is enhanced using a PCMCIA design supporting
30 cards for multiple functions and tasks. Alternatively the corresponding circuitry may be directly incorporated onto the unit's motherboard (similar to the design of Figure 3A) or placed onto a daughterboard interfacing the ISA bus 356. The latter design

may have a lower EVL hardware cost.

A third embodiment will be quickly described with reference to Figure 3C. In this embodiment, box 320 represents the data processing and information management function. Data processing power has been increased to the level of an
5 integrated 486 type microprocessor 322 with approximately 256 kilobytes of flash memory 321 and 1 megabyte of DRAM 323. The processor interfaces with a data and information display and control function 335 including a keyboard or other input (not shown), touchscreen, or LCD, LCD controller and memory 336.

To receive input and provide output externally, there are provided parallel port
10 341 of the processor and serial port 342 of an external interface 340. Through the external interface 340, there pass cellular phone data, roadside reader or tag data, GPS data, satellite communications data (such as LEOSAT) and Qualcomm OmniTrax data.

There is also provided a PC-104 mezzanine interface.

15 To obtain vehicle and other sensor data, there is an eight channel analog sensor interface 330 designated 331 through which multi-sensor data is acquired. As has already been described, the sensors obtain safety, emission, cargo security and vehicle security and safety data among other data.

EVL data information storage and retrieval are represented by box 325
20 including a first and second PCMCIA interface 326 and 327 for electronic credential data of driver, cargo and vehicle.

Now referring to Figure 4, the operation of processors 302, 351 or equivalent processors will be described in connection with the formation of protected data packets (PDP's). Generally, Figure 4 represents the creation of the log memory of
25 the Electronic Vehicle Log (EVL) 1 of the present invention. The protection provided for EVL memory 430 is described by outer dashed line box 433 as comprising a password and/or speaker verification. Via link 431 an EVL-unique secret key is provided to processor and DRAM 400 (for example, processor 302, 351).

30 Via link 401, the processor gathers the vehicle location data and via link 402 the processor gathers date and real time data, for example, from the same source 303 or 380 as described earlier in connection with Figures 3A and 3B.

Processor 400 also obtains vehicle sensor data via link 403, credentials and event data via link or links 404 and cargo status data via link 405.

The output of the processor 400 is a protected data packet forwarded via link 420 to a non-volatile log memory 410, for example, similar in form to variable data 308a or memory 370. An expanded view of the contents of a protected data packet 411 of the present invention is represented by block 411. The protected data packet 411 contains logged information 420a, a real time of day and date stamp 420b, a vehicle location stamp 420c, the unique vehicle identification 420d and an electronic signature 420e formed as will be described herein.

Logged information 420a may represent a printed page scanned from a page scanner or more data and thus may comprise megabytes of memory. On the other hand, a date and time stamp 420b may comprise just a hundred bytes of memory or less, for example, representing approximately twenty ASCII characters. Vehicle location data 420c including latitude and longitude may require ten to twenty bytes. Likewise, a vehicle identifier 420d may comprise just the equivalent of about twenty ASCII characters. On the other hand, the electronic signature 420e may require 200 bytes of data.

In general, the EVL log data will be generated using the following steps: 1) Data for logging will be acquired from various sources including, but not limited to, on-vehicle sensors, external systems and cargo monitors. The types of data logged and methods for acquiring the data have been described already above. 2) When a log entry is to be made, the EVL processor 400 will obtain the current date and time of day, vehicle location (at least in the form of latitude and longitude and possibly in the form of map location data such as route and mileage along a route from a given point), the EVL secret key and the EVL unique identification data. The processes for obtaining that data have likewise been described above. 3) The EVL processor prepares a protected data packet (PDP) using the information from step 2. The processor computes the packet's electronic signature 420e using a secure hash algorithm, a public key encryption algorithm and the EVL secret key. The PDP is then stored on the data logging medium (card, disk or the like).

Public key/private key encryption algorithms are known in the art including one formerly licensed through PKP Partners (a partnership of RSA and Cylink, which

has recently been ordered dissolved by an arbitrator in California). Another is promoted through the National Institute of Standards and Technologies in Gaithersburg, Maryland (N.I.S.T.). US Patents numbered 4,405,829, 4,424,414, 4,200,770, 4,218,582, 4,995,082 and 5,231,668 describe this technology.

5 Once the data has been logged into the EVL, various methods may be used to transmit or transport the PDP's to other systems which may require the information (owners, drivers or governmental authorities). Additional encryption techniques may be used during transmission to prevent information from becoming available to unauthorized third parties who may be tapping the communications channel.

10 Now, data logging, authenticated data distribution, secure data transmission and credential storage operations will be described with reference to Figures 4A and 4B. Figure 4B shows the public key encryption pairs used by different authorities. First, data logging will be described in the context of the driver entering log data by way of example. When the vehicle is to be used, the driver inserts the removable
15 non-volatile log memory 430 for the duration of the trip. For example, a driver may obtain access and log into the EVL by inputting their speech, a password or a biometric 433 after inserting their card memory 430. Upon successful recognition of the password or biometric and/or verification of the speaker's identity or after completion of both processes, the driver-unique data is used to decrypt a secret or
20 private key member (for example, 451a which is never released from secure memory) of a public key encryption pair 451a and 451b. When data is to be logged by the driver, protected data packets containing this log data are generated with digital signatures formed by encrypting digital hash values with this secret key member 451a of the public key pair.

25 Now, authenticated data distribution will be described. Protected data packets (PDP's) 420 are transmitted to a requesting user via electronic means, for example, wireless, telephone modem or a memory card. The requesting user has a trusted (escrowed) copy of the public key 451b of the above-referenced public key pair 451a, 451b, the pair including the secret key 451a (which never leaves secure memory)
30 used for forming the electronic signature. The public key 451b is used to verify that the electronic signature of the PDP is accurate. Correct verification of the electronic signature then confirms the data source (the driver-protected secret key 451a) and the

integrity of the data (since the hash value matches the PDP data).

Secure data transmission from one party to another or intra-party will now be described. A governmental authority may obtain access by a defined process. One example of such a process for obtaining an early transmission of vehicle data in advance of a border crossing or like event is described by the following. The agency wishing to receive secure data generates a public key encryption pair 452a, 452b different from that used by the driver and distributes the public key portion 452b to any person or system desiring to transmit secure data. The public key portion 452b is stored in EVL memory. A profile of a commercial vehicle and a cargo may be extracted from the vehicle via a card memory or may be electronically extracted by wireless means prior to the vehicle's departure and delivered to the authority with the stored public key portion 452b. The EVL generates a private encryption key 431 and uses it to encrypt PDP's with their corresponding digital signatures. The EVL encrypts this private encryption key 431 using the public key 452b and transmits that information to the agency receiving the data. The receiving agency decrypts the EVL private encryption key 431 using the secret key portion 452a of the key pair 452a, 452b and then decrypts the PDP's using the decrypted key 431. The profile and public key 452b are transmitted via a centralized authority data base to regional data bases for distribution to checkpoints, port of entry border crossings and the like along the intended route of the vehicle.

As the vehicle approaches the inspection facility, the vehicle is polled or interrogated, for example, preferably by wireless means in advance of reaching the facility so the vehicle need not stop its movement. The vehicle transmitted profile data is compared with the previously transmitted profile data and the inspector may preclear the vehicle through the inspection station. If the inspection data is a weigh station, for example, and data is to be entered into the log by the authority, an electronic signature is utilized to verify the entered data, preventing subsequent modifications of the logged information. Moreover, at the time the entry is made, the vehicle position and time from the global positioning system may be automatically and simultaneously recorded, allowing detection of fraudulent entries. As the vehicle crosses the border, a short range communications system may be used to verify that the vehicle crossing the border is the vehicle which received the preclearance to

cross.

It is also possible that the vehicle may carry all the profile information in the EVL and transit the data via wireless means to the authority just a few minutes before arrival or before the approval (for example, preapproval at a border crossing) event.

5 In this case and in that described above as well, some sort of short range transmission is useful as the vehicle crosses the border to physically confirm that the vehicle crossing the border is the same as the one that provided the profile and credentials data and received preapproval to cross.

10 Finally, credential data storage will be described in some detail. An authorized individual such as an inspector or police officer creates a digital credential in a generating device's memory, for example, a laptop personal computer. A secret key 454a of a public key pair 454a, 454b is used to generate a digital signature for the credential data. The credential and signature are transmitted to the EVL using various means, possibly including wireless means, direct input (typing), or memory card transfer. This transfer may be encrypted as discussed above as desired. for 15 wireless or other secure data transmission. The credential and signature are formed into a PDP and logged as described above for the driver data logging operation. When the credential is subsequently transmitted to a requesting agency, the agency will use a trusted copy of the public key portion 454b to verify the electronic signature of the PDP. 20

The EVL will internally store the data for subsequent display, processing or transmission. Much of the data stored will be sensitive. For example, the tariff-related data may be used to facilitate international border crossing and if this data could be electronically forged, it would result in a loss of revenue or worse. The storage techniques described above respond to this need for data security. The storage approach is also related to the data reception and transmission approaches described above and further in the following discussion. 25

A wide variety of media and storage techniques are currently available, several have been described above. One form is a removable non-volatile memory. This may comprise flash memory or other non-volatile memory adapted to form a removable unit such as a PCMCIA card. One or more of these cards may comprise the EVL. 30

Another memory is a removable disk drive. This may comprise a floppy disk drive or removable hard disk drive such as one, likewise mounted on a PCMCIA card. This may likewise be secure enough to form an EVL.

An internal non-volatile memory or disk drive may likewise comprise an EVL.
5 This storage device may be hosted entirely within the EVL housing 300, 350 of Figures 3A or 3B. In one embodiment, it may not be removed without destruction of the data contained within.

In yet another embodiment of the present invention, an internal volatile memory may be used as an EVL if protected from erasure, for example, by a battery
10 or other power back-up device permanently associated therewith.

On the other hand, removable memory will allow a certified person to place credentials or event data on the storage device by removing it from the EVL housing, placing it into another electronic device (such as a portable computer), and writing the credentials in a secure manner onto the memory device. Non-volatile memory
15 would require an interface between the EVL housing and the certified persons' electronic device. This interface could be either wired or wireless (radio frequency).

Typically each discrete group of information to be protected is processed by assembling the data in an area of volatile memory. The date and time of the packet creation are obtained from a reliable source and added to the packet. GPS and a
20 clock internal to the EVL are possible sources. The position of the vehicle at the time of the packet creation are obtained from a reliable source and added to the packet. GPS and Loran are possible sources. The EVL unique identification data is obtained and added to the packet. A secure hash value is computed for the packet from the above-acquired data. The secure hash value is then encrypted using the
25 EVL unique secret key from a public key encryption key pair. The encrypted secure hash value, then, is the electronic signature for the packet which may be recovered by those having the key to the exclusion of others. Packets with their corresponding signatures are stored in the EVL on the various storage media chosen for the application as described above.

30 The addition of reliable date, time of day, and location data is a significant security feature. It can prevent an unscrupulous person skilled in the art of computer hardware and software manipulation from forging protected data packets and inserting

them into the EVL memory when the EVL is at a location inconsistent with the legitimate position or at a time inconsistent with an expected time of day for legitimate packet creation.

To prevent unscrupulous, technically adept persons from obtaining illicit
5 access to the EVL Secret Key and creating forged PDP's, the EVL secret key and
EVL unique identification data may be further protected using other cryptographic or
other technologies. For example, the EVL secret key and identification data may be
encrypted by a password known only by the user (such as the driver). The user
(driver) would be required to enter their password prior to the start of transit or the
10 entry of their data. The unencrypted data would be maintained only as long as the
vehicle travels and adheres to an intended route or defined itinerary prestored with
the password of the driver.

As a further security means, PDP generation may be contingent upon
successful completion of a Speaker Verification function within the EVL. For
15 example, the EVL may include a speaker verification (identity verification) and
speech recognition (password recognition) subsystem or subsystems which verbally
accepts the password used to decrypt the EVL secret key and EVL identification data.
If the registered vehicle driver's voice is not confirmed (through speaker verification,
for example), then the PDP encryption is not performed.

20 Figure 5A provides a table as an example of a memory table of protected data
packets that may be maintained in an in-vehicle database (EVL) according to the
method of Figure 4. One item may be the vehicle identification data which uniquely
identify at least the vehicle. In particular, however, for a particular trip, the data
ideally describes a unique driver, a unique cab and a unique trailer or trailers if
25 pulling more than one trailer at a time or during a route. Vehicle classification data
may describe the type of vehicle/trailer(s) and an oversize or overweight condition.
For example, some states require no trailer(s) having a greater length than a
predetermined length for safety reasons as automobiles allegedly are unable to pass
such long trailers. Vehicle height limits are important for bridge and tunnel
30 construction. Weight limits are imposed for highways because overweight vehicles
are an important cause of the failure of roadways over time.

Another data item is cargo description. Their are various types including

"hazardous" cargos that require special handling and special routing. Quantity must be logged and maintained for certain tariffs are based on quantity rather than weight or size. Cargo security is important to the trucker as well as the owner of the cargo. The cargo security is protected by bonding, by assuring environmental factors and the like. The cargo destination may vary with the route. Cargo is deposited and new cargo is picked up requiring new credential data be entered.

Route data comprises the following: intended route and intended stops along the way, alternate routes, expected times of arrival and destinations along the route. This data may be stored in the form of maps and compared with GPS data by appropriate algorithms to determine deviations from intended routes.

Safety information can contain inspections, dates of inspections, records of the inspections, and measurements taken. For example, brakes, engine failure, tire safety and the like, signal indicators and the like may be regarded over time.

Other credential data includes licenses permits, inspections, reports, trip logs of other trips, and manifests. This data is not intended to be entirely inclusive.

Over time, data may be tabulated and summarized and output in the form of Figure 5B. For example, brake performance can demonstrate over time the mechanical status and history of the cab and trailer(s) brakes. Moreover, over time, the driver status and history may be recorded. For example, the driver can collect road mileage, time or duration of travel for the mileage logged and health record. More particularly, the driver's vision, alcohol or drug record and the like can be maintained with the driver's identification. Figure 5B also refers to environmental systems for detecting temperature, pressure and the like which are factors of the environment of the vehicle, driver and cargo. Inspection records and on-board monitors and sensor data is recorded in an environmental system table over time.

Figures 6A and 6B provide charts showing several applications of the present invention identified as to service, application, technology or product applicable for providing that application, what can be demonstrated and its use. Figure 6B is merely a continuation of Figure 6A.

The following services are performed by the present invention in combination with external systems as required: commercial fleet management so that a fleet operator may maintain data on their fleet of vehicles, emergency notification and

personal security, hazardous material and incident notification, commercial vehicle electronic clearance and administrative procedures for state and international border crossing, automated roadside safety inspections and on-board safety monitoring. The reader will please refer to the charts for application, technology or product available, demonstration and utilization information for each of these.

Thus there has been shown and described an electronic vehicle log and security method therefore by which different users may apply their own electronic signatures and secure their own data for later retrieval. Data packets are protected from unscrupulous individuals who would forge data by not only protecting the packets via public key/private key encryption but by voice security and real time of day and location data. Deviations from the present invention may be practiced for any more of the services of Figures 6A and 6B or other services that may come to mind from a reading of the present application. Any pending applications or patents mentioned above should be deemed to be incorporated by reference as to any material contained therein that is essential to a proper understanding of the present invention's manufacture or use. The present invention should only be deemed to be limited by the scope of the claims which follow.

WHAT IS CLAIMED IS:

1. Apparatus for maintaining a log of credential data secure from an uncertified user comprising
a processor for forming protected data packets comprising at least the credential data and an electronic signature representing a certified user and
5 a memory for storing the protected data packets.
2. Log maintenance apparatus according to claim 1 further comprising means for providing date and time of day data for inclusion in the protected data packets.
- 10 3. Log maintenance apparatus according to claim 2 further comprising an interface to said processor for receiving vehicle location data.
4. Log maintenance apparatus according to claim 1 further comprising an interface to sensors for sensing in-transit data.
5. Log maintenance apparatus according to claim 1 further comprising an
15 interface to means for obtaining cargo monitoring data.
6. Log maintenance apparatus according to claim 1 further comprising an interface to means for obtaining event data.
7. Log maintenance apparatus according to claim 3 wherein said protected data packets comprise credential data, date and time data, vehicle location data
20 vehicle identification data and the electronic signature.
8. Log maintenance apparatus according to claim 3 further comprising a microphone coupled to said processor, said processor receiving voice samples via the microphone for comparison with voice data stored in the memory.
9. A vehicular data processing method for use by a vehicle in interacting
25 with an in-transit facility comprising the steps of:
communicating with the in-transit facility;
receiving a polling signal;
responsive to the polling signal, transmitting at least vehicle credential data;
and
30 receiving a bypass signal or a stop signal, the bypass signal indicating that the vehicle may pass and the stop signal indicating the vehicle must stop.
10. The data processing method of claim 9 wherein

preliminary to the transmitting step, generating protected data packets comprising the credential data and an electronic signature.

11. The data processing method of claim 10 wherein preliminary to the transmitting step, collecting data representing the date and
5 time of day for inclusion in the protected data packet.

12. The data processing method of claim 9 wherein preliminary to the transmitting step, collecting data representing the location of the vehicle for inclusion in the protected data packet.

13. The data processing method of claim 9 wherein
10 preliminary to the transmitting step, collecting data representing a unique vehicle identification for inclusion in the protected data packet.

14. The data processing method of claim 9 wherein the electronic signature comprises a secure hash value computed for the packet encrypted using a secret key from a public key encryption key pair.

15. A method of generating protected data packets for storage in an electronic vehicle log comprising the steps of

collecting data to be protected,
collecting data representing date and time of day,
collecting vehicle location data,
20 retrieving vehicle identification data,
generating an electronic signature from one or more of the collected and retrieved data, and

storing the protected data packet including the data to be protected, the date and time of day, the vehicle location, the vehicle identification and the electronic
25 signature.

16. The method of claim 15 wherein said electronic signature is generated by performing the steps of computing a secure hash value for the packet and encrypting the secure hash value using the secret key of a public key encryption key pair.

17. The method of claim 15 further comprising the steps of a user speaking
30 a password for comparison with a password stored for the user.

18. The method of claim 15 further comprising the steps of

- storing a private encryption key,
encrypting protected data packets for transmission using the private encryption
key and
transmitting the protected packet using a public key pair different from one
5 used in generating the electronic signature.
19. The method of claim 15 comprising the steps of
generating event data and
generating a further electronic signature for the event data using a public key
pair different from one used in generating the electronic signature.
- 10 20. The method of claim 15 comprising the steps of
storing intended vehicle route data,
comparing the collected vehicle location data with the intended vehicle route
data and
determining if the protected data packet is valid from the result of the
15 comparison step.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US95/12459

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This international report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

2. Claims Nos.:
because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

Please See Extra Sheet.

1. As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- The additional search fees were accompanied by the applicant's protest.
 No protest accompanied the payment of additional search fees.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US95/12459

BOX II. OBSERVATIONS WHERE UNITY OF INVENTION WAS LACKING

This ISA found multiple inventions as follows:

This application contains the following inventions or groups of inventions which are not so linked as to form a single inventive concept under PCT Rule 13.1. In order for all inventions to be examined, the appropriate additional examination fees must be paid.

Group I, claims 1-8 and 15-20, drawn to a system of generating and maintaining a log.

Group II, claims 9-14, drawn to a method for use by a vehicle for interacting with an in-transit facility.

The inventions listed as Groups I and II do not relate to a single inventive concept under PCT Rule 13.1 because, under PCT Rule 13.2, they lack the same or corresponding special technical features for the following reasons:

Group I lacks the technical features of Group II representing its inventive concept, "communicating with the in-transit facility," "receiving a polling signal" from an in-transit facility, "transmitting vehicle credential data" to the facility, and "receiving a bypass or a stop signal." Further, Group II lacks the technical features of Group I, forming and storing "protected data packets."

(54) Title: MOTOR VEHICLE MONITORING SYSTEM FOR DETERMINING A COST OF INSURANCE

(57) Abstract

A method and system of determining a cost of automobile insurance based upon monitoring, recording and communicating data representative of operator and vehicle driving characteristics (202). The cost is adjustable retrospectively and can be prospectively set by relating the driving characteristics to predetermined safety standards. The method comprises steps of monitoring a plurality of raw data elements (208) representative of an operating state of the vehicle or an action of the operator. Selected ones of the raw data elements are recorded when the ones are determined to have an identified relationship to safety standards. The selected ones are consolidated (210) for processing against an insurer profile and for identifying a surcharge or discount (214) to be applied to a base cost of automobile insurance. A final cost (216) is produced from the base costs and the surcharges and discounts.

MOTOR VEHICLE MONITORING SYSTEM FOR DETERMINING A COST OF INSURANCE

Background of the Invention

The present invention relates to data acquisition and processing systems, and particularly to a system for monitoring motor vehicle operational characteristics and driver behavior to obtain increased amounts of data relating to the safety of use for purposes of providing a more accurate determination of a cost of insurance for the vehicle.

Conventional methods for determining costs of motor vehicle insurance involve gathering relevant historical data from a personal interview with the applicant for the insurance and by referencing the applicant's public motor vehicle driving record that is maintained by a governmental agency, such as a Bureau of Motor Vehicles. Such data results in a classification of the applicant to a broad actuarial class for which insurance rates are assigned based upon the empirical experience of the insurer. Many factors are relevant to such classification in a particular actuarial class, such as age, sex, marital status, location of residence and driving record.

The current system of insurance creates groupings of vehicles and drivers (actuarial classes) based on the following types of classifications.

Vehicle:

Age;
manufacturer, model; and
value.

Driver:

Age;
sex;
marital status;
driving record (based on government reports),
violations (citations);

at fault accidents; and
place of residence.

Coverage:

5 Types of losses covered,
 liability,
 uninsured motorist,
 comprehensive, and
 collision;
10 liability limits; and
 deductibles.

 The classifications, such as age, are further broken into actuarial
classes, such as 21 to 24, to develop a unique vehicle insurance cost based on
the specific combination of actuarial classes for a particular risk. For example,
the following information would produce a unique vehicle insurance cost.

15

Vehicle:

Age	1993 (three years old)
manufacturer, model	Ford, Explorer XLT
value	\$ 18,000.

20

Driver:

Age	38 years old
sex	male
marital status	single
driving record (based on government reports)	
violations	1 point (speeding)
at fault accidents	3 points (one at fault accident)
place of residence	33619 (zip code)

25

Coverage:

Types of losses covered

	liability	yes
	uninsured motorist	no
	comprehensive	yes
	collision	yes
5	liability limits	\$100,000./\$300,000./\$50,000.
	deductibles	\$500./\$500.

A change to any of this information would result in a different premium being charged, if the change resulted in a different actuarial class for that variable. For instance, a change in the drivers' age from 38 to 39 may not result in a different actuarial class, because 38 and 39 year old people may be in the same actuarial class. However, a change in driver age from 38 to 45 may result in a different premium because of the change in actuarial class.

Current insurance rating systems also provide discounts and surcharges for some types of use of the vehicle, equipment on the vehicle and type of driver. Common surcharges and discounts include:

Surcharges:

Business use.

Discounts:

Safety equipment on the vehicle
 airbags, and
 antilock brakes;
 theft control devices
 passive systems (e.g. "The Club"), and
 alarm system; and
 driver type
 good student, and
 safe driver (accident free).

A principal problem with such conventional insurance determination systems is that much of the data gathered from the applicant in the interview is not verifiable, and even existing public records contain only minimal information, much of which has little relevance towards an assessment of the likelihood of a claim subsequently occurring. In other words, current rating systems are primarily based on past realized losses. None of the data obtained through conventional systems necessarily reliably predicts the manner or safety of future operation of the vehicle. Accordingly, the limited amount of accumulated relevant data and its minimal evidential value towards computation of a fair cost of insurance has generated a long-felt need for an improved system for more reliably and accurately accumulating data having a highly relevant evidential value towards predicting the actual manner of a vehicle's future operation.

Many types of vehicle operating data recording systems have heretofore been suggested for purposes of maintaining an accurate record of certain elements of vehicle operation. Some are suggested for identifying the cause for an accident, others are for more accurately assessing the efficiency of operation. Such systems disclose a variety of conventional techniques for recording vehicle operation data elements in a variety of data recording systems. In addition, it has also been suggested to provide a radio communication link for such information via systems such as a cellular telephone to provide immediate communication of certain types of data elements or to allow a more immediate response in cases such as theft, accident, break-down or emergency. It has even been suggested to detect and record seatbelt usage to assist in determination of the vehicle insurance costs (U.S. Patent No. 4,667,336).

The various forms and types of vehicle operating data acquisition and recordal systems that have heretofore been suggested and employed have met with varying degrees of success for their express limited purposes. All possess substantial defects such that they have only limited economical and

practical value for a system intended to provide an enhanced acquisition, recordal and communication system of data which would be both comprehensive and reliable in predicting an accurate and adequate cost of insurance for the vehicle. Since the type of operating information acquired and recorded in prior art systems was generally never intended to be used for determining the cost of vehicle insurance, the data elements that were monitored and recorded therein were not directly related to predetermined safety standards or the determining of an actuarial class for the vehicle operator. For example, recording data characteristics relevant to the vehicle's operating efficiency may be completely unrelated to the safety of operation of the vehicle. Further, there is the problem of recording and subsequently compiling the relevant data for an accurate determination of an actuarial profile and an appropriate insurance cost therefor.

Current motor vehicle control and operating systems comprise electronic systems readily adaptable for modification to obtain the desired types of information relevant to determination of the cost of insurance. Vehicle tracking systems have been suggested which use communication links with satellite navigation systems for providing information describing a vehicle's location based upon navigation signals. When such positioning information is combined with roadmaps in an expert system, vehicle location is ascertainable. Mere vehicle location, though, will not provide data particularly relevant to safety of operation unless the data is combined with other relevant data in an expert system which is capable of assessing whether the roads being driven are high-risk or low-risk with regard to vehicle safety.

The present invention contemplates a new and improved motor vehicle monitoring, recording and communication system, which primarily overcomes the problem of determining cost of vehicle insurance based upon data which does not take into consideration how a specific vehicle is operated. The subject invention will base insurance charges with regard to current material data representative of actual driving characteristics of the vehicle and driver operation

to provide a classification rating of the operator and the vehicle in an actuarial class which has a vastly reduced rating error over conventional insurance cost systems. Additionally, the present invention allows for frequent (monthly) adjustment to the cost of coverage because of the changes in operator behavior and driving patterns. This can result in automobile insurance charges that are readily controllable by individual operators. The system is adaptable to current electronic operating systems, tracking systems and communication systems for the improved extraction of selected insurance related data.

10 Brief Summary of the Invention

In accordance with the present invention, there is disclosed a method of determining a cost of automobile insurance based upon monitoring, recording and communicating data representative of operator and vehicle driving characteristics, whereby the cost is adjustable by relating the driving characteristics to predetermined safety standards. The method is comprised of steps of monitoring a plurality of raw data elements representative of an operating state of a vehicle or an action of the operator. Selected ones of the plurality of raw data elements are recorded when they are determined to have an identified relationship to the safety standards. The recorded elements are consolidated for processing against an insured profile and for identifying a surcharge or discount to be applied to a base cost of automobile insurance. The total cost of insurance obtained from combining the base cost and surcharges or discounts is produced as a final cost to the operator.

25 In accordance with another aspect of the present invention, the recording comprises identifying a trigger event associated with the raw data elements which has an identified relationship to the safety standards so that trigger information representative of the event is recorded.

In accordance with a more limited aspect of the present invention, the method comprises a step of immediately communicating to a central control

station via an uplink, information representative of the trigger event and recording response information generated by the control station.

5 In accordance with yet another aspect of the present invention, the method comprises steps of generating calculated data elements and derived data elements from the raw data elements, and accumulating the calculated and derived data elements in a recording device.

10 The present invention will use information acquired from the vehicle to more accurately assess vehicle usage and thereby derive insurance costs more precisely and fairly. Examples of possible actuarial classes developed from vehicle provided data include:

Driver:

- 15 Total driving time in minutes by each driver of the insured vehicle;
- number of minutes driving in high/low risk locations (high/low accident areas);
- number of minutes of driving at high/low risk times (rush hour or Sunday afternoon);
- safe driving behavior,
 - 20 using seat belts,
 - use of turn signals,
 - observance of speed limits, and
 - observance of traffic control devices;
 - number of sudden braking situations; and
 - number of sudden acceleration situations.

25 **Vehicle:**

- Location vehicle is parked at night (in garage, in driveway, on street);
- and
- location vehicle is parked at work (high theft locations, etc.).

These new and more precise actuarial classes are considered to be better predictors of loss because they are based on actual use of the vehicle and the behaviors demonstrated by the driver. This will allow the consumers unprecedented control over the ultimate cost of their vehicle insurance.

5 In accordance with the present invention, additional discounts and surcharges based on data provided by the insured vehicle will be available. Examples of surcharges and discounts based on vehicle provided data include:

Surcharges:

10 Excessive hard braking situations occurring in high risk locations; and intermittent use of a safety device, such as seat belts.

Discounts:

15 Regular selection of low/high risk routes of travel;
regular travel at low/high risk times;
significant changes in driving behavior that results in a lower risk;
vacation discount when the vehicle is not used;
regular use of safety devices; and
unfailing observance of speed limits.

20 There is some overlap between the use of actuarial classes and discounts and surcharges. Until data has been gathered and analyzed it is not possible to determine which vehicle provided data will be used to determine actuarial classes and which will be used for surcharges or discounts.

25 One benefit obtained by use of the present invention is a system that will provide precise and timely information about the current operation of an insured motor vehicle that will enable an accurate determination of operating characteristics, including such features as miles driven, time of use and speed of the vehicle. This information can be used to establish actual usage based insurance charges, eliminating rating errors that are prevalent in traditional

systems and will result in vehicle insurance charges that can be directly controlled by individual operators.

It is another benefit of the subject invention that conventional motor vehicle electronics are easily supplemented by system components comprising a data recording, a navigation system and a communications device to extract selected insurance relevant data from the motor vehicle.

It is yet another object of the present invention to generate actuarial classes and operator profiles relative thereto based upon actual driving characteristics of the vehicle and driver, as represented by the monitored and recorded data elements for providing a more knowledgeable, enhanced insurance rating precision.

The subject new insurance rating system retrospectively adjusts and prospectively sets premiums based on data derived from motor vehicle operational characteristics and driver behavior through the generation of new actuarial classes determined from such characteristics and behavior, which classes heretofore have been unknown in the insurance industry. The invention comprises an integrated system to extract via multiple sensors, screen, aggregate and apply for insurance rating purposes, data generated by the actual operation of the specific vehicle and the insured user/driver.

Other benefits and advantages of the subject new vehicle insurance cost determination process will become apparent to those skilled in the art upon a reading and understanding of the specification.

Brief Description of the Drawings

The invention may take physical form in certain parts and steps and arrangements of parts and steps, the preferred embodiments of which will be described in detail in this specification and illustrated in the accompanying drawings which form a part hereof and wherein:

FIGURE 1 is a flowchart generally describing a data gathering process from a vehicle;

5 FIGURE 2 is a flowchart detailing the gathering and consolidating of appropriate information for determining a cost of insurance and the resulting insurance billing process;

FIGURE 3 is a suggestive perspective drawing of a vehicle including certain data element monitoring, recording and communicating devices;

10 FIGURE 4 is a block diagram of a vehicle on-board computer and recording system implementing the subject invention for selective communication with a central control center and a global positioning navigation system;

FIGURE 5 is a flowchart generally illustrating a method for acquiring and recording vehicle insurance related data; and

15 FIGURE 6 a tabular illustration of various sources of insurance-related data, a necessary interface for acquiring the data and an exemplary sample rate therefor.

Detailed Description of the Invention

20 Referring now to the drawings, wherein the showings are for purposes of illustrating the preferred embodiments of the invention only and not for purposes of limiting same, the FIGURES show an apparatus and method for monitoring, recording and communicating insurance related data for determination of an accurate cost of insurance based upon evidence relevant to the actual operation and in particular the relative safety of that operation.

25 Generally, a vehicle user is charged for insurance based upon statistical averages related to the safety of operation based upon the insurer's experience with other users who drive similar vehicles in a similar geographic area. The invention allows for the measure of the actual data while the motor vehicle is being driven. Such data measurement will allow the vehicle user to directly control

his/her insurance costs by operating the vehicle in a manner which he/she will know will evidence superior safety of operation and a minimal risk of generation of an insurance claim. Examples of data which can be monitored and recorded include:

5

1. Actual miles driven;
2. Types of roads driven on (high risk vs. low risk); and,
3. Safe operation of the vehicle by the vehicle user through:
 - A. speeds driven,
 - 10 B. safety equipment used, such as seat belt and turn signals,
 - C. time of day driven (high congestion vs. low congestion),
 - D. rate of acceleration,
 - 15 E. rate of braking,
 - F. observation of traffic signs.

With reference to FIGURE 3, an exemplary motor vehicle is shown in which the necessary apparatus for implementing the subject invention is included. An on-board computer 300 monitors and records various sensors and operator actions to acquire the desired data for determining a fair cost of insurance. Although not shown therein, a plurality of operating sensors are associated with the motor vehicle to monitor a wide variety of raw data elements. Such data elements are communicated to the computer through a connections cable which is operatively connected to the vehicle data bus 304 through an SAE-J1978 connector, or OBD-II connector or other vehicle sensors 306. A driver input device 308 is also operatively connected to the computer 300 through connector 307 and cable 302. The computer is powered through the car battery 310 or a conventional generator system (not shown). Tracking of

the vehicle for location identification can be implemented by the computer 300 through navigation signals obtained from a GPS (global positioning system) antenna or other locating system 312. The communications link to a central control station is accomplished through the cellular telephone, radio, satellite or other wireless communication system 314.

FIGURE 4 provides the block diagram of the in-vehicle computer system. The computer 300 is comprised of four principal components, an on-board data storage device 402, an input/output subsystem 404 for communicating to a variety of external devices, a central processing unit and memory device 406 and a real time operating kernel 408 for controlling the various processing steps of the computer 300. The computer 300 essentially communicates with three on-board vehicle devices for acquisition of information representative of various actual vehicle operating characteristics. A driver input console 410 allows the driver to input data representative of a need for assistance or for satisfaction of various threshold factors which need to be satisfied before the vehicle can be operated. The physical operation of the vehicle is monitored through various sensors 412 in operative connection with the vehicle data bus, while additional sensors 414 not normally connected to the data bus can be in direct communication with the computer 300 as will hereinafter be more fully explained.

The vehicle is linked to an operation control center 416 by a communications link 418, preferably comprising a conventional cellular telephone interconnection. A navigation sub-system 420 receives radio navigation signals from a GPS 422.

The type of elements monitored and recorded by the subject invention comprise raw data elements, calculated data elements and derived data elements. These can be broken down as follows:
